Citation Fønhus MS, Dalsbø TK, Brurberg KG. Facemasks to prevent transmission of respiratory illness, such as COVID-19 - a rapid overview of systematic reviews [Munnbind for å forhindre smitte av luftveisinfeksjoner, som covid-19 – en hurtigoversikt 2021]. Oslo: Norwegian Institute of Public Health, 2021

Plain language summary

In March 2021 we searched for systematic reviews that analyse and summarise the effectiveness of facemasks on respiratory virus transmission, such as COVID-19. We found one systematic review of high quality.

This high-quality systematic review analyses and summarises the effectiveness of facemasks versus no facemasks or different types of facemasks. All types of populations and settings are included. We have communicated the relevant findings of this systematic review as a short communication product called [«Briefly summarised»](#). This systematic review searched for studies in April 2020 and does not include studies on COVID-19. Thus, this high-quality systematic review provides indirect evidence regarding COVID-19.

In the process of making this rapid overview we found that it would be very helpful to make a thorough map of the relevant primary studies included in the systematic reviews in one place.

Hovedfunn (Norwegian)

I mars 2021 søkte vi etter systematiske oversikter som analyserer og oppsummerer effekten av å bruke munnbind på smitte av luftveisinfeksjoner, som covid-19. Vi fant én systematisk oversikt av høy kvalitet.

Denne høykvalitetsoversikten analyserer og oppsummerer effekten av å bruke munnbind sammenlignet med ingen munnbind eller ulike typer munnbind eller masker. Alle typer populasjoner og settinger er inkludert. Vi har laget en kort oppsummering av relevante funn i et kort kommunikasjonsprodukt som heter [«Briefly summarised»](#) («Kort oppsummert» på norsk).

Den systematiske oversikten søkte etter studier i april 2020 og omfatter ingen studier om covid-19. Denne høykvalitetsoversikten presenterer dermed kun indirekte forskning med hensyn til Covid-19.

I arbeidet med denne hurtigoversikten, fant vi at en grundig kartlegging av de relevante primærstudiene som er med i de systematiske oversiktene, vil være nyttig å samle på ett sted.

Background

Respiratory infections can be caused by many viruses such as influenza virus, rhinovirus, adenovirus, and coronavirus. Most of them cause mild respiratory illness. However, some viruses can cause severe respiratory illness that can result in hospitalisation and death.

Viral respiratory infections can be a serious threat, especially if they become epidemic or pandemic. Vaccines and medical treatments may not be enough to prevent their spread and other strategies to prevent transmission is necessary. Like other respiratory viral illnesses, the coronavirus disease 2019 (COVID-19) is transmitted by the respiratory route.

COVID-19 can spread from an infected person’s mouth or nose in small liquid particles when they cough, sneeze, speak, sing, or breathe heavily. The virus can also spread after infected people sneeze, cough on, or touch surfaces, or objects, such as tables, doorknobs, and handrails. Other people may become infected by touching these contaminated surfaces, then touching their eyes, noses or mouths without having cleaned their hands first ([WHO 2020](#)).

To prevent the spread of COVID-19, the most common strategies have been to promote appropriate physical distance, good hand hygiene, and facemask use. The use of facemasks has received a great deal of attention. It has been debated both politically, and in the mass media as well as social media. Although being debated, it seems that facemask use is perceived to be an effective mean of reducing transmission. This perception has contributed to a political imperative to encourage or mandate the use of facemasks in the public.

In response to the COVID-19 outbreak, the international research community has published numerous systematic reviews on the effectiveness of facemask use on respiratory virus transmission. However, the production of robust research takes time, and systematic reviews appear to summarise many of the same few primary studies. With the increasing number of systematic reviews published, we will here attempt to guide decisionmakers to high-quality systematic reviews that can support well-informed decisions about the effectiveness of facemask use on respiratory virus transmission.

Purpose

The purpose of this overview was to find high-quality systematic reviews that assess the effectiveness of facemask use on respiratory illness transmission, including COVID-19.

Method

This is a rapid overview where we have used a transparent and systematic approach.

The protocol of this rapid overview of systematic reviews was pre-registered on the [Open Science Framework](#) February 22, 2021.

Inclusion criteria, PICO

Our inclusion criteria were broad and are described in table 1. We only included systematic reviews that analyse and summarise the effectiveness of facemask use in primary studies (we excluded umbrella reviews, overviews, recommendations etc.).

Table 1. PICOS (Population, Intervention, Comparison, Outcome, Setting)

P opulation:	All
I ntervention:	Facemask (all types of facemasks)
C omparison:	No facemask use, other interventions, or comparisons of different types of facemasks
O utcomes:	At least one of the following two outcomes: Number of people with viral respiratory infection (laboratory-confirmed) Number of people with respiratory illness or influenza-like illness (clinical symptoms)
S etting:	All

Search

We searched for systematic reviews in Cochrane Library, Epistemonikos, Google Scholar, MedRxiv, and PubMed March 9-10, 2021 with different search terms for facemasks (see [Appendix 1](#)).

We searched for systematic reviews published after the outbreak of COVID-19 (published between 2020 and 2021). The search strategy was checked by an information specialist and carried out by one of the authors.

Selection of systematic reviews

Two authors independently screened titles and abstracts according to the inclusion criteria. We retrieved full-text copies of all papers that were potentially relevant, including those where the description of the population, intervention, comparison, outcomes, or setting was insufficient in the abstract to decide about inclusion.

Two authors independently assessed the full-text copies of the papers for relevance. We resolved any disagreements by discussion and consensus with a third author. We kept a log of the selection process to complete a PRISMA flow diagram ([Moher 2009](#)).

We described studies that initially appeared to meet the inclusion criteria but later were excluded, including the reasons for exclusion.

Assessment of the methodological quality of the systematic reviews

Systematic reviews are considered the gold standard for evidence used to evaluate the effectiveness of healthcare interventions. Some systematic reviews may be of poor quality because they have been designed, conducted, or reported inappropriately. Poorly conducted systematic reviews can lead to inaccurate effect estimates, misleading conclusions, or reduced applicability, all of which are a waste of limited resources ([Chalmers and Glasziou 2009](#)).

We assessed the quality in two steps:

1. An initial short step where three questions must be answered with 'yes' to be further considered for a more comprehensive quality assessment. These questions are:
 - a) Is it clear what the population(s), intervention(s), comparison(s), and outcomes are?
 - b) Has the identification of research studies been described with where they searched (databases), how they searched (search terms), and when they searched (search date)?
 - c) Have the included studies been judged for methodological quality (risk of bias)?
2. A comprehensive quality assessment of systematic reviews that fulfilled all three criteria from the first initial short step of quality assessment. We used [AMSTAR 2](#).

Results

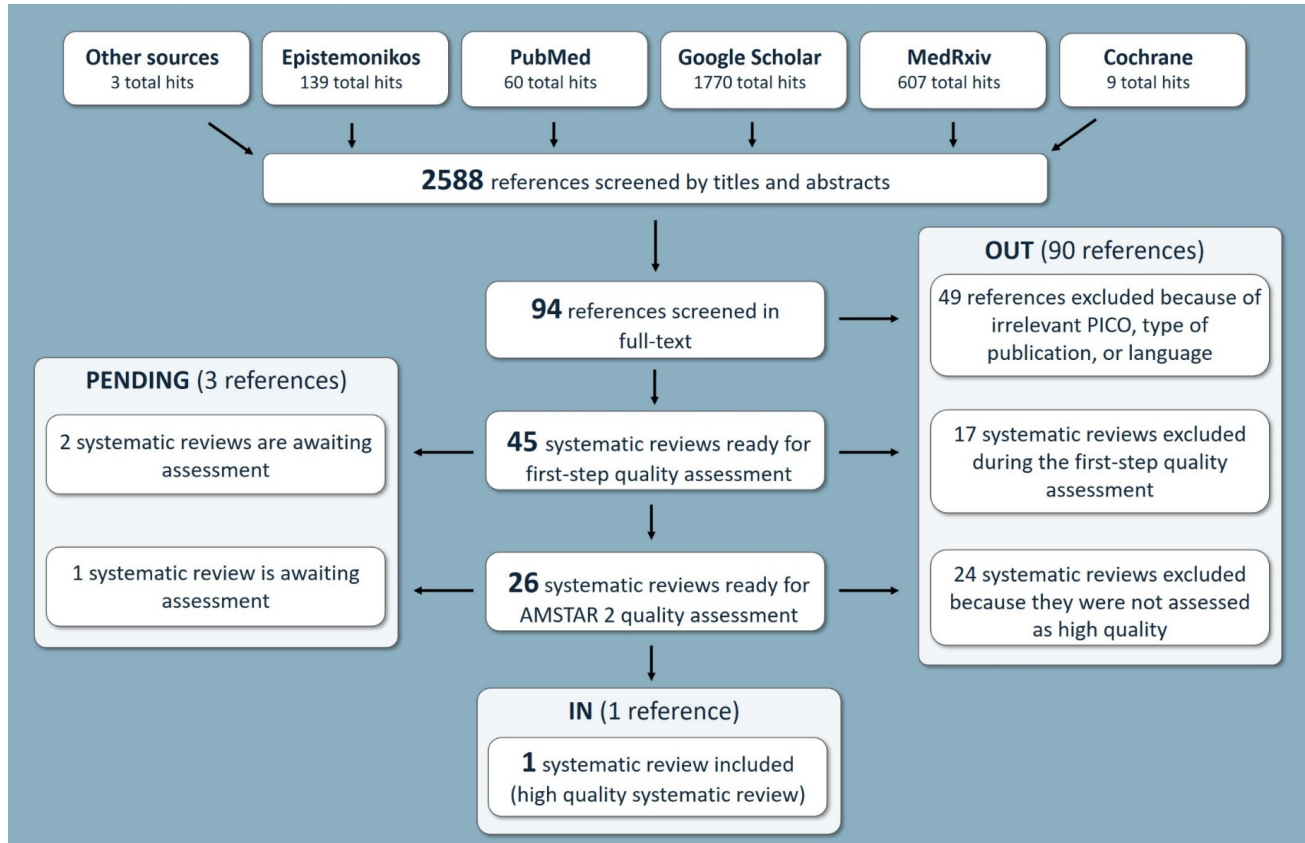

Identification of systematic reviews ready for AMSTAR 2 quality assessment

One author searched in Cochrane Library, Epistemonikos, Google Scholar, MedRxiv, and PubMed March 9-10, 2021 and found 2585 references. We also found three references through other sources. The total number of references were then 2588.

The titles and abstracts of these references were independently screened by two authors (see figure 1). We agreed on which references we needed in full text to assess for inclusion.

We retrieved 94 references in full text, and two authors independently assessed their relevance for inclusion. We excluded 49 full text references for different reasons (see [Appendix 2](#)). Thus, we considered 45 of totally 94 references to be systematic reviews. Most of these systematic reviews (36 SRs) could be found through searches in Epistemonikos. Of the nine systematic reviews that could not be found in Epistemonikos five systematic reviews could only be found through searches in Google Scholar and one each in MedRxiv, PubMed and other sources (Google). One systematic review could be found both in Google Scholar and MedRxiv.

Figure 1. Flow chart of the selection process

Two authors independently performed an initial short quality assessment to identify systematic reviews eligible for AMSTAR 2 quality assessment. Of the 45 systematic reviews assessed in an initial short quality step, 26 were considered ready for AMSTAR 2 quality assessment. We excluded 17 systematic reviews due to different limitations and two could not be assessed at this point (see [Appendix 2](#)).

From the 26 systematic reviews ready for AMSTAR 2 assessment, almost all (23 SRs) were identified through searches in Epistemonikos ([Aggarwal 2020](#); [Bartoszko 2020](#); [Barycka 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Iannone 2020](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#); [Tabatabaeizadeh 2021](#); [Wang 2020](#); [Wu 2020](#); [Yin 2021](#)) while two were found through Google Scholar ([Brainard 2020](#); [Rohde 2020](#)) and one through other sources (Google) ([Rees 2020](#)).

PICO information from the systematic reviews

One author extracted PICO information from the 26 systematic reviews (SRs) ([Aggarwal 2020](#); [Bartoszko 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Iannone 2020](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rees 2020](#); [Rohde 2020](#); [Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#); [Tabatabaeizadeh 2021](#); [Wang 2020](#); [Wu 2020](#); [Yin 2021](#)) that were ready to be quality assessed by AMSTAR 2, and the other author double-checked. We present the results in table 2.

Populations and settings

From table 2 you can see that most of the systematic reviews (22 SRs) include a broad non-specific population ([Aggarwal 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rees 2020](#); [Rohde 2020](#); [Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#); [Tabatabaeizadeh 2021](#); [Wang 2020](#)) while a small number have a more narrow population, such as healthcare workers (four SRs) ([Bartoszko 2020](#); [Iannone 2020](#); [Wu 2020](#); [Yin 2021](#)).

Most of the systematic reviews (14 SRs) include all types of settings ([Barycka 2020](#); [Brainard 2020](#); [Chou 2020](#); [Chu 2020](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Santos 2020](#); [Sharma 2020](#); [Tabatabaeizadeh 2021](#)) while a few include community settings (six SRs) ([Aggarwal 2020](#); [Coclite 2021](#); [Rees 2020](#); [Rohde 2020](#); [Siegfried 2020](#); [Wang 2020](#)) or healthcare settings (four SRs) ([Iannone 2020](#); [Mondal 2020](#); [Wu 2020](#); [Yin 2021](#)). Two systematic reviews did not report specifically on setting ([Bartoszko 2020](#); [Camargo 2020](#)).

Interventions and comparisons

Most of the systematic reviews (14 SRs) define their intervention more generally as 'facemasks' ([Aggarwal 2020](#); [Brainard 2020](#); [Chu 2020](#); [Coclite 2021](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rohde 2020](#); [Tabatabaeizadeh 2021](#); [Yin 2021](#)) while others define the types of facemasks, such as 'medical masks' (two SRs) ([Bartoszko 2020](#); [Barycka 2020](#)), 'N95 respirators' (two SRs) ([Iannone 2020](#); [Long 2020](#)), 'cloth masks' (three SRs) ([Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#)), 'non-woven facemasks' ([Camargo 2020](#)), 'surgical masks' ([Wang 2020](#)), 'medical masks and N95 respirators' (two SRs) ([Rees 2020](#); [Wu 2020](#)), or 'N95 respirators, surgical masks, and cloth masks' ([Chou 2020](#)).

The comparisons are defined as 'no facemasks or other interventions' (five SRs) ([Aggarwal 2020](#); [Brainard 2020](#); [Jefferson 2020](#); [Nanda 2021](#); [Wang 2020](#)), 'no facemasks' (six SRs) ([Camargo 2020](#); [Coclite 2021](#); [Kim 2021](#); [Ollila 2020](#); [Rees 2020](#); [Rohde 2020](#)), 'control' (two SRs) ([Li 2020](#); [Liang 2020](#)), other types of facemasks, respirators or respiratory protective devices (12 SRs) ([Bartoszko 2020](#); [Barycka 2020](#); [Chou 2020](#); [Chu 2020](#); [Iannone 2020](#); [Long 2020](#); [Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#); [Tabatabaeizadeh 2021](#); [Wu 2020](#); [Yin 2021](#)), or not prespecified ([Mondal 2020](#)).

Outcomes

All the systematic reviews report on outcomes on respiratory virus transmission. They report respiratory virus transmission as respiratory illness symptoms, either self-reported or clinically verified, (19 SRs) ([Aggarwal 2020](#); [Bartoszko 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Iannone 2020](#); [Jefferson 2020](#); [Long 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rees 2020](#); [Rohde 2020](#); [Santos 2020](#); [Siegfried 2020](#); [Wang 2020](#); [Yin 2021](#)) or lab-confirmed respiratory virus infection (21 SRs) ([Bartoszko 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Iannone 2020](#); [Jefferson 2020](#); [Kim 2021](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Mondal 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rees 2020](#); [Rohde 2020](#); [Santos 2020](#); [Siegfried 2020](#); [Tabatabaeizadeh 2021](#); [Wang 2020](#); [Yin 2021](#)). A few did not specify how the respiratory virus infection was measured in the studies they included ([Coclite 2021](#); [Sharma 2020](#); [Wu 2020](#)).

Table 2. PICO information from systematic reviews assessed with AMSTAR 2

Exp.= experimental, HCWs= healthcare workers, Obs.=observational, RCTs= randomised controlled trials, RPPE= respiratory personal protective equipment SRs= systematic reviews * Only studies that are included in the results (not discussion) that fit our PICO (not necessary the same as the total number reported in the systematic review) ** We have only included studies from their own primary analysis, not SRs or other meta-analysis the systematic reviews may have included

How up to date are the systematic reviews?

Most of the systematic reviews' literature searches were carried out between December 2019 and June 2020 (20 SRs) ([Aggarwal 2020](#); [Bartoszko 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Camargo 2020](#); [Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Iannone 2020](#); [Jefferson 2020](#); [Liang 2020](#); [Long 2020](#); [Mondal 2020](#); [Rees 2020](#); [Santos 2020](#); [Sharma 2020](#); [Siegfried 2020](#); [Wang 2020](#); [Wu 2020](#); [Yin 2021](#)) while a few were carried out between August 2020 and November 2020 ([Kim 2021](#); [Li 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rohde 2020](#); [Tabatabaeizadeh 2021](#)).

COVID-19 direct evidence

Some systematic reviews (eight SRs) include primary studies that have assessed facemask use and COVID-19 infection transmission ([Chu 2020](#); [Coclite 2021](#); [Li 2020](#); [Liang 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rohde 2020](#); [Tabatabaeizadeh 2021](#)). Of these COVID-19 primary studies, one is a randomised controlled trial (RCT) two are cohort studies, 10 are case-control studies, three are cross-sectional studies, and four are modelling studies.

The results of the AMSTAR 2 quality assessments

One systematic review ([Kim 2021](#)) could not be quality assessed with AMSTAR 2 and is awaiting assessment (see [Appendix 2](#) for more details). Two authors independently assessed the quality of the remaining 25 systematic reviews with AMSTAR 2 (see [Appendix 3](#) for more details) and came to agreement on the final assessments.

We assessed one systematic review as having critically low quality ([Mondal 2020](#)), 10 as having low quality ([Aggarwal 2020](#); [Camargo 2020](#); [Li 2020](#); [Liang 2020](#); [Long 2020](#); [Rohde 2020](#); [Sharma 2020](#); [Tabatabaeizadeh 2021](#); [Wang 2020](#); [Yin 2021](#)), 13 as having moderate quality ([Bartoszko 2020](#); [Barycka 2020](#); [Brainard 2020](#); [Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Iannone 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Rees 2020](#); [Santos 2020](#); [Siegfried 2020](#); [Wu 2020](#)), and one as having high quality ([Jefferson 2020](#)) (see table 3).

The main reasons why we rated most systematic reviews to moderate or low quality are that:

- they do not provide information about a protocol or predefined selection criteria on their work (64% of the SRs) – item 2 in AMSTAR 2
- they do not provide information about excluded studies (84% of the SRs) – item 7 in AMSTAR 2
- they do not provide information about how or if the included studies were funded (92% of the SRs) – item 10 in AMSTAR 2
- they do not assess the potential impact of risk of bias in individual studies on the meta-analysis (83% of the SRs) – item 12 in AMSTAR 2

Furthermore, we found only eight systematic reviews that fully fulfil the criteria described for a comprehensive literature search strategy ([Chou 2020](#); [Chu 2020](#); [Coclite 2021](#); [Jefferson 2020](#); [Li 2020](#); [Ollila 2020](#); [Santos 2020](#); [Sharma 2020](#)) (item 4 in AMSTAR 2). Also, remarkably few (5 SRs) fully fulfil the criteria for good descriptions of included studies ([Chou 2020](#); [Jefferson 2020](#); [Nanda 2021](#); [Ollila 2020](#); [Sharma 2020](#)) (item 8 in AMSTAR 2).

AMSTAR 2 checklist. CL= critically low quality, H= high quality, L= low quality, M= moderate quality N/A= not applicable

Detailed PICO information from the high-quality systematic review

We extracted more detailed PICO-information from the high-quality systematic review ([Jefferson 2020](#)) (see table 4). The authors include only randomised controlled trials and have no limits regarding populations or settings. They include all types of facemasks and all types of comparisons (including comparisons of different types of facemasks against each other). We have communicated the relevant findings of this systematic review as a short communication product called [«Briefly summarised»](#).

This high-quality systematic review ([Jefferson 2020](#)) searched for studies in April 2020 and does not include primary studies on COVID-19. Thus, this high-quality systematic review provides indirect evidence regarding COVID-19.

Table 4. Detailed PICO table of the high-quality systematic review, Jefferson 2020

PICO	What did they search for?	What did they find?
Study design	RCTs (randomised controlled trials)	All 67 studies were RCTs, of which 19 involved facemask use. 15 RCTs were presented in Summary of findings tables (SoFs)
Population	All populations	Community, including students, pilgrims, families, and health care workers. Three of the 15 studies presented in SoFs were among healthcare workers (Ide 2016; Jacobs 2009; MacIntyre 2015), whilst the remaining studies were among non-healthcare workers (students, households, families, or pilgrims).
Intervention and comparison	Physical interventions (including facemasks)	<p>19 RCTs about facemasks (Aelami 2015; Aiello 2010; Aiello 2012; Barasheed 2014; Canini 2010; Cowling 2008; Cowling 2008; Ide 2016; Jacobs 2009; Larson 2010; Loeb 2009; MacIntyre 2009; MacIntyre 2011; MacIntyre 2013; MacIntyre 2015; MacIntyre 2016; Radonovich 2019; Simmerman 2011; Suess 2012).</p> <p>Relevant comparisons presented in Summary of Findings tables: Face mask versus no facemask (10 studies) (Aiello 2010; Aiello 2012; Barasheed 2014; Canini 2010; Cowling 2008; Jacobs 2009; MacIntyre 2009; MacIntyre 2015; MacIntyre 2016; Suess 2012). One study compared catechin-treated masks to no mask (Ide 2016), and one study included cloth masks versus control (third arm in MacIntyre 2015). Surgical/medical mask and cloth mask and N95/P2 (5 studies) (Loeb 2009; MacIntyre 2009; MacIntyre 2011; MacIntyre 2013; Radonovich 2019).</p> <p>Other relevant facemask comparisons not presented in Summary of Findings tables: Facemask + hand hygiene versus control (6 studies) (Aelami 2015; Aiello 2012; Cowling 2009; Larson 2010; Simmerman 2011; Suess 2012) Facemask + hand hygiene versus hand hygiene (3 studies) (Cowling 2009; Larson 2010; Simmerman 2011). Duration of the intervention among the 15 studies included in this summary, when described, mainly varied from one week to 5 months. Except for 1 study (Radonovich 2019) where health care workers used facemask for 1 year or more when they were in close contact with patients who had acute respiratory illness. Most of the time is also included soap, hand sanitizing, or information material. Control groups usually also got information or educational material.</p>
Outcomes	Respiratory illness Influenza-like illness Laboratory-confirmed influenza Harms / adverse events Deaths Severity of viral illness Absenteeism Hospital admission Illness related complications	<p>Analysis were made for the following outcomes: Clinical respiratory illness Influenza-like illness Laboratory-confirmed influenza Harms / adverse events</p> <p>They found no data for the following outcomes from facemask studies: Deaths Severity of viral illness Absenteeism Hospital admission Illness-related complications</p>
Setting	All countries and all settings	Most studies took place during the influenza season during autumn or winter in the community. One study was conducted during H1N1 pandemic season (Suess 2012). One study was conducted on household individuals (MacIntyre 2009), 5 studies included healthcare workers either in a hospital setting, (Loeb 2009; MacIntyre 2011; MacIntyre 2013), or an outpatient setting (MacIntyre 2009; Radonovich 2019).
Certainty of evidence	They used GRADE to assess the certainty of the evidence.	Very low, low, and moderate evidence due to lack of blinding, imprecision, and inconsistency.
Relevant COVID-19 studies published after the last update		Bundgaard 2020

Discussion

There are many systematic reviews that address the effectiveness of facemasks on respiratory viral infection transmission. We found, surprisingly, only one of these ([Jefferson 2020](#)) to be of high quality. All of the systematic reviews except five ([Mondal 2020](#); [Ollila 2020](#); [Rees 2020](#); [Siegfried 2020](#); [Wu 2020](#)) had been peer-reviewed. Our quality assessments did not seem to differ among peer-reviewed and non-peer-reviewed systematic reviews.

Previous evaluations of the quality of systematic reviews for other types of effectiveness questions have concluded that many systematic reviews have poor quality ([Wasiak 2017 A](#); [Wasiak 2017 B](#); [Opheim 2019](#); [Wei 2020](#)), and that this very much is the case also for COVID-19 related meta-analyses ([Pires 2021](#)).

To conduct a trustworthy high-quality systematic review authors have access to good and free sources, such as The Cochrane Handbook ([Higgins 2021](#)). Although it takes time and effort to conduct a high-quality systematic review, most of the shortcomings identified during our AMSTAR 2 quality assessment were issues that were more around how well authors describe what they did. These issues are not particularly time-consuming to address but require a clear purpose and a solid plan of how the work will be carried out and described. Thus, if authors are more transparent, explicit, and descriptive in their work with a systematic review, most of the systematic reviews would probably get a higher quality score.

The main purpose for conducting a systematic review should be that it can be used for making well-informed decisions. If readers are going to put things into practise, they need more information than what most systematic reviews provide. For topics or questions where many systematic reviews exist, it is even more important to make good justifications for making new systematic reviews. If good and sound justifications are made it might reduce the number and hopefully raise the quality. The situation we face today is very unsatisfying and is deemed to confuse decision-makers as a redundant pool of systematic reviews on the exact same topic exists (see figure 2).

In 2016 there were 22 systematic reviews published every day ([Page 2016](#)). The number of systematic reviews published is thus assumed to have by-passed the number of randomised controlled trials ([Ioannidis 2016](#)). Today's situation has become an overload of systematic reviews. This is the opposite of what the evidence-based medicine intentions are.

Conclusion

We here provide a 'quick snapshot overview' of published systematic reviews on facemasks. The effectiveness of facemasks on viral respiratory infection transmission appears to be a highly prioritised question since we found as many as 43 systematic reviews published within the last year. However, only one of these has high quality. We have communicated the relevant findings of this systematic review as a short communication product called [«Briefly summarised»](#). This systematic review should be updated as soon as possible to help evidence-based practice and well-informed decisions. With relatively few and easy-to-do improvements, many more of the systematic reviews assessed in this overview, could end up on high quality.

Our work and findings have also pointed out that it may be helpful to map all relevant primary studies and retrieve enough information from each study at one place. This 'one place', should be a map of primary studies that is up to date and can function as a primary source for making meta-analyses or other types of analyses.

Figure 2. An illustration of the ideal versus non-ideal evidence-based decision-making situation

Table 1. Pending references (3 references)

Reference	Title	Reason	Pending until
Dugré 2020	Masks for prevention of viral respiratory infections among health care workers and the public: PEER umbrella systematic review	Waiting assessment. Search terms not described in the article and supplementary information about search not available from webpage March 2021. Thus, not able to perform quality step 1.	If no information is available within 2021, we will exclude the systematic review.
Kim 2021	Comparative Efficacy of N95, Surgical, Medical, and Non-Medical Facemasks in Protection of Respiratory Virus Infection: A Living Systematic Review and Network Meta-Analysis	Waiting assessment. Under review process, so supplemental material from preprint version is not available March 2021. Thus, not able to perform quality step 2 (AMSTAR 2)	If no information is available within 2021, we will exclude the systematic review.
Saijonkai 2020	Face masks for preventing respiratory infections in the community: A systematic review	Waiting assessment. Search terms not described in the article and supplementary information about search not available from webpage March 2021. Thus, not able to perform quality step 1.	If no information is available within 2021, we will exclude the systematic review.

Zhang 2020	The role of isolation rooms, facemasks and intensified hand hygiene in the prevention of nosocomial COVID-19 transmission in a pulmonary clinical setting	Not a SR

PICO= Poulation, Intervention, Comparison, Outcome, **SR**= systematic review

Table 3. Excluded systematic reviews, first round of quality assessment (17 references)

Reference	Title	Reason
Abborah-Offei 2021	A rapid review of the use of face mask in preventing the spread of COVID-19	No RoB
Chaabna 2021	Facemask use in community settings to prevent respiratory infection transmission: a rapid review and meta-analysis	No RoB
Daoud 2021	The Potential for Cloth Masks to Protect Health Care Clinicians From SARS-CoV-2: A Rapid Review	No RoB
De Angelis 2020	Hand hygiene and facemask use to prevent droplet transmitted viral diseases during air travel: a systematic literature review	No RoB
Dehqani 2020	Face masks vs. COVID-19: a systematic review	No RoB
Gupta 2020	The use of facemasks by the general population to prevent transmission of Covid 19 infection: A systematic review	No RoB
Jain 2020	Efficacy and Use of Cloth Masks: A Scoping Review	No RoB
Juneau 2020	Evidence-Based, Cost-Effective Interventions To Suppress The COVID-19 Pandemic: A Systematic Review	No RoB
MacIntyre & Chughtai 2020	A rapid systematic review of the efficacy of face masks and respirators against coronaviruses and other respiratory transmissible viruses for the community, healthcare workers and sick patients	No RoB
Marasinghe 2020	Face mask use among individuals who are not medically diagnosed with COVID-19: A lack of evidence for and against and implications around early public health recommendations	No RoB
Mostafaei 2020	Can Wearing a Face Mask Protect from COVID-19? A Systematic Review	No RoB
Perski 2020	Face masks to prevent community transmission of viral respiratory infections: A rapid evidence review using Bayesian analysis	Inaccurate search
Sharma & Kant 2020	Who should use a face mask during COVID-19 pandemic? An evidence-based review	No RoB
Silva 2020	Cloth masks as respiratory protections in the COVID-19 pandemic period: evidence gaps	No RoB
Taminato 2020	Homemade cloth face masks as a barrier against respiratory droplets - systematic review	No RoB
Wei 2020	Facemasks prevent influenza-like illness: implications for COVID-19	No search terms
Xiao 2020	Nonpharmaceutical Measures for Pandemic Influenza in Nonhealthcare Settings-Personal Protective and Environmental Measures	No RoB

RoB= risk of bias

Items in AMSTAR

1	Did the research questions and inclusion criteria for the review include the components of PICO?
2	Did the report of the review contain an explicit statement that the review methods were established prior to the conduct of the review and did the report justify any significant deviations from the protocol?
3	Did the review authors explain their selection of the study designs for inclusion in the review?
4	Did the review authors use a comprehensive literature search strategy?
5	Did the review authors perform study selection in duplicate
6	Did the review authors perform data extraction in duplicate?
7	Did the review authors provide a list of excluded studies and justify the exclusions?
8	Did the review authors describe the included studies in adequate detail?
9	Did the review authors use a satisfactory technique for assessing the risk of bias (RoB) in individual studies that were included in the review?
10	Did the review authors report on the sources of funding for the studies included in the review?
11	If meta-analysis was performed did the review authors use appropriate methods for statistical combination of results?
12	If meta-analysis was performed, did the review authors assess the potential impact of RoB in individual studies on the results of the meta-analysis or other evidence synthesis?
13	Did the review authors account for RoB in individual studies when interpreting/ discussing the results of the review?
14	Did the review authors provide a satisfactory explanation for, and discussion of, any heterogeneity observed in the results of the review?
15	If they performed quantitative synthesis did the review authors carry out an adequate investigation of publication bias (small study bias) and discuss its likely impact on the results of the review?
16	Did the review authors report any potential sources of conflict of interest, including any funding they received for conducting the review?

Scores in AMSTAR

High - Zero or one non-critical weakness: The systematic review provides an accurate and comprehensive summary of the results of the available studies that address the question of interest

Moderate - More than one non-critical weakness*: The systematic review has more than one weakness, but no critical flaws. It may provide an accurate summary of the results of the available studies that were included in the review.

Low - One critical flaw with or without non-critical weaknesses: The review has a critical flaw and may not provide an accurate and comprehensive summary of the available studies that address the question of interest.

Critically low - More than one critical flaw with or without non-critical weaknesses: The review has more than one critical flaw and should not be relied on to provide an accurate and comprehensive summary of the available studies.
