A B S T R A C T

Background

Healthcare professionals are important contributors to healthcare quality and patient safety, but their performance does not always follow recommended clinical practice. There are many approaches to influencing practice among healthcare professionals. These approaches include audit and feedback, reminders, educational materials, educational outreach visits, educational meetings or conferences, use of local opinion leaders, financial incentives, and organisational interventions. In this review, we evaluated the effectiveness of patient-mediated interventions. These interventions are aimed at changing the performance of healthcare professionals through interactions with patients, or through information provided by or to patients. Examples of patient-mediated interventions include 1) patient-reported health information, 2) patient information, 3) patient education, 4) patient feedback about clinical practice, 5) patient decision aids, 6) patients, or patient representatives, being members of a committee or board, and 7) patient-led training or education of healthcare professionals.

Objectives

To assess the effectiveness of patient-mediated interventions on healthcare professionals’ performance (adherence to clinical practice guidelines or recommendations for clinical practice).

Search methods

We searched MEDLINE, Ovid in March 2018, Cochrane Central Register of Controlled Trials (CENTRAL) in March 2017, and ClinicalTrials.gov and the International Clinical Trials Registry (ICTRP) in September 2017, and OpenGrey, the Grey Literature Report and Google Scholar in October 2017. We also screened the reference lists of included studies and conducted cited reference searches for all included studies in October 2017.

Selection criteria

Randomised studies comparing patient-mediated interventions to either usual care or other interventions to improve professional practice.
Data collection and analysis

Two review authors independently assessed studies for inclusion, extracted data and assessed risk of bias. We calculated the risk ratio (RR) for dichotomous outcomes using Mantel-Haenszel statistics and the random-effects model. For continuous outcomes, we calculated the mean difference (MD) using inverse variance statistics. Two review authors independently assessed the certainty of the evidence (GRADE).

Main results

We included 25 studies with a total of 12,268 patients. The number of healthcare professionals included in the studies ranged from 12 to 167 where this was reported. The included studies evaluated four types of patient-mediated interventions: 1) patient-reported health information interventions (for instance information obtained from patients about patients’ own health, concerns or needs before a clinical encounter), 2) patient information interventions (for instance, where patients are informed about, or reminded to attend recommended care), 3) patient education interventions (intended to increase patients’ knowledge about their condition and options of care, for instance), and 4) patient decision aids (where the patient is provided with information about treatment options including risks and benefits). For each type of patient-mediated intervention a separate meta-analysis was produced.

Patient-reported health information interventions: probably improve healthcare professionals’ adherence to recommended clinical practice (moderate-certainty evidence). We found that for every 100 patients consulted or treated, 26 (95% CI 23 to 30) are in accordance with recommended clinical practice compared to 17 per 100 in the comparison group (no intervention or usual care). We are uncertain about the effect of patient-reported health information interventions on desirable patient health outcomes and patient satisfaction (very low-certainty evidence). Undesirable patient health outcomes and adverse events were not reported in the included studies and resource use was poorly reported.

Patient information interventions may improve healthcare professionals’ adherence to recommended clinical practice (low-certainty evidence). We found that for every 100 patients consulted or treated, 32 (95% CI 24 to 42) are in accordance with recommended clinical practice compared to 20 per 100 in the comparison group (no intervention or usual care). Patient information interventions may have little or no effect on desirable patient health outcomes and patient satisfaction (low-certainty evidence). We are uncertain about the effect of patient information interventions on undesirable patient health outcomes because the certainty of the evidence is very low. Adverse events and resource use were not reported in the included studies.

Patient education interventions probably improve healthcare professionals’ adherence to recommended clinical practice (moderate-certainty evidence). We found that for every 100 patients consulted or treated, 46 (95% CI 39 to 54) are in accordance with recommended clinical practice compared to 35 per 100 in the comparison group (no intervention or usual care). Patient education interventions may slightly increase the number of patients with desirable health outcomes (low-certainty evidence). Undesirable patient health outcomes, patient satisfaction, adverse events and resource use were not reported in the included studies.

Patient decision aid interventions may have little or no effect on healthcare professionals’ adherence to recommended clinical practice (low-certainty evidence). We found that for every 100 patients consulted or treated, 32 (95% CI 24 to 43) are in accordance with recommended clinical practice compared to 37 per 100 in the comparison group (usual care). Patient health outcomes, patient satisfaction, adverse events and resource use were not reported in the included studies.

Authors’ conclusions

We found that two types of patient-mediated interventions, patient-reported health information and patient education, probably improve professional practice by increasing healthcare professionals’ adherence to recommended clinical practice (moderate-certainty evidence). We consider the effect to be small to moderate. Other patient-mediated interventions, such as patient information may also improve professional practice (low-certainty evidence). Patient decision aids may make little or no difference to the number of healthcare professionals’ adhering to recommended clinical practice (low-certainty evidence).

The impact of these interventions on patient health and satisfaction, adverse events and resource use, is more uncertain mostly due to very low certainty evidence or lack of evidence.

Plain Language Summary

Patient-mediated interventions to improve professional practice

What is the aim of the review?
Our aim with this Cochrane review was to assess whether patients can change the performance of healthcare professionals. We collected and analysed all relevant studies to answer this question and found 25 studies.

**Key message**

This review suggests that patients may change healthcare professionals’ practice through the following three strategies: 1) strategies where patients give healthcare professionals information about themselves; 2) strategies where patients are given healthcare information; and 3) strategies where patients take part in patient education. Patient decision aids may make little or no difference to healthcare professionals’ practice, however, the certainty is low, and these results should be interpreted carefully. We still need more research about the best ways in which patients can change professional practice and about the impact it has on patients’ health.

**What was studied in the review?**

Many strategies have been tested to see if they can improve healthcare professionals’ practice and make sure that patients receive the best available care. These strategies include sending reminders to healthcare professionals, giving them further education, or giving them financial rewards. These strategies have mostly had only small or moderate effects. Another way of changing what healthcare professionals do is through the patients themselves. These strategies are called ‘patient-mediated interventions’.

**What are the main results of the review?**

The studies in this review assessed different patient-mediated strategies compared to usual care or no strategies.

**Strategies where patients give information to healthcare professionals**

In these studies, patients gave information about their own health, concerns or needs to the doctor. This was usually done by filling in a questionnaire in the waiting area before a consultation. The doctor was then given this information before or at the consultation. The review shows that these strategies:

- probably improve the extent to which healthcare professionals follow recommended clinical practice (moderate-certainty evidence).

We are uncertain about the effect of these strategies on patient health, patient satisfaction and resource use because these outcomes were not measured in the studies or because the certainty of the evidence is very low.

**Strategies where information was given to patients**

In these studies, patients were given information about recommended care or were reminded to use services, for instance to go for a check-up. The review shows that these strategies:

- may improve the extent to which healthcare professionals follow recommended clinical practice (low-certainty evidence);

- may have little or no effect on patient satisfaction (low-certainty evidence);

- may have little or no effect on some patient health outcomes, such as the number of patients who reach controlled blood pressure (low-certainty evidence). However, we are uncertain about the effect of these strategies on other patient health outcomes because the certainty of the evidence is very low. We also lack information to draw conclusions about resource use.

**Patient education strategies**

In these studies, patients took part in patient education such as self-management programmes, for instance to increase their knowledge about their condition. The review shows that these strategies:

- probably improve the extent to which healthcare professionals follow recommended clinical practice (moderate-certainty evidence);

- may slightly improve some patient health outcomes such as the number of patients who reach controlled blood pressure (low-certainty evidence). However, we are uncertain about the effect of these strategies on other patient health outcomes, patient satisfaction and resource use because these outcomes were not measured in the included studies.

**Patient decision aid strategies**

In the one study that assessed effect of patient decision aids, patients were given a decision aid consisting of a booklet, personal worksheet, and audiotape to make decisions about their medical management. The review shows that these strategies:

- may have little or no effect on the extent to which healthcare professionals follow recommended clinical practice (low-certainty evidence)
We are uncertain about the effect of these strategies on patient health, patient satisfaction and resource use because these outcomes were not measured in the studies or because the certainty of the evidence is very low.

**How up-to-date is this review?**

We searched for studies up to March 2018 and ongoing studies up to October 2017.
### Patient-reported health information interventions versus comparisons to improve professional performance

**Patient or population:** general patient population, “at risk” patient population and patient population with a specific condition or disease

**Setting:** primary care (mostly)

**Intervention:** patient-reported health information interventions

**Comparison:** no intervention or usual care

<table>
<thead>
<tr>

## Undesirable patient health outcomes

None of the included studies reported on undesirable patient health outcomes.

## Patient satisfaction

<table>
<thead>
<tr>
<th>Number of satisfied patients (0-3 months follow-up)</th>
<th>38 per 100 (49 to 100)</th>
<th>94 per 100 (74 to 100)</th>
<th>RR 2.45 (1.27 to 4.74)</th>
<th>26 (1 RCT)</th>
<th>VERY LOW</th>
</tr>
</thead>
</table>

We are uncertain about the effect of patient-reported health information interventions on the number of satisfied patients because the certainty of the evidence is very low.

<table>
<thead>
<tr>
<th>The mean patient satisfaction score was 4.3 points higher (0.12 higher to 0.68 higher)</th>
<th>79 (1 RCT)</th>
<th>VERY LOW</th>
</tr>
</thead>
</table>

We are uncertain about the effect of patient-reported health information interventions on the degree of patient satisfaction because the certainty of the evidence is very low.

## Adverse events

None of the included studies reported on adverse events.

## Resource use (0-3 months follow-up)

The findings are narratively presented in Table 3. The researchers in this study reported a total cost of 69.20 US $ per child.

<table>

CI: Confidence interval; RR: Risk ratio, RCT: randomised trial.
GRADE Working Group grades of evidence

**High certainty:** This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different** is low.

**Moderate certainty:** This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different** is moderate.

**Low certainty:** This research provides some indication of the likely effect. However, the likelihood that it will be substantially different** is high.

**Very low certainty:** This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different** is very high.

**Substantially different** = a large enough difference that it might affect a decision.

---

1. Downgraded one level because we judged only 1 of 4 studies to have low risk of bias
2. Downgraded one level because we judged the study to have potential risk of bias
3. Downgraded two levels for imprecision because of very few events (and one small study only)
4. Downgraded two levels for imprecision because of a very small sample size (and one small study only)

**BACKGROUND**

**Description of the condition**

Healthcare professionals’ performance is not always in line with recommended clinical practices (McGlynn 2003; Runciman 2012; Schuster 1998; Seddon 2001). Reducing the gap between recommended and actual clinical practice is a key element of healthcare quality improvement. Recommended practices are typically formulated in clinical practice guidelines. Clinical practice guidelines have the potential to improve the quality of healthcare and patient outcomes by providing specific recommendations for professional practice (Grol 2003; Schuster 1998; Seddon 2001). Adherence to clinical practice guidelines is thus frequently used as a measure of the quality of healthcare. Various interventions are proposed as means to improve the performance of healthcare professionals, e.g. audit and feedback, reminders, educational material, educational outreach visits, educational meetings or conferences, use of local opinion leaders, financial incentives, organisational interventions, and patient-mediated interventions.

**Description of the intervention**

Several definitions of patient-mediated intervention have been proposed (Grimshaw 2004; Légaré 2014; Robertson 2006). Here we define patient-mediated interventions according to Légaré 2014: “any intervention aimed at changing the performance of healthcare professionals through interactions with patients, or information provided by or to patients”.

Overall, experimental studies of interventions to improve professional practice have yielded small to moderate effects. A Cochrane review shows that audit and feedback probably improves professional practice, but the effectiveness ranges from little or no effect to a substantial effect (Ivers 2012). Reminders, such as computer-generated reminders delivered on paper to healthcare professionals, probably improve professional practice (Arditi 2017). Printed educational material may also improve professional practice, but the effect seems small, and the certainty of the evidence is low (Giguère 2012). Educational meetings or educational outreach visits may result in modest improvements in professional practice (Forsetlund 2009; O’Brien 2007). Using local opinion leaders may improve professional practice (Flodgren 2011a), as may financial incentives (Flodgren 2011b). Another recent Cochrane review shows that healthcare professionals provided with clinical practice guidelines accompanied by tools developed by guideline producers probably adhere more to clinical guidelines (Flodgren 2016). Organisational interventions, such as provision of pharmaceutical care, medication reviews, and follow-up visits by a healthcare professional including a pharmacist, nurse or physician, probably make little or no difference to the number of medication errors by primary healthcare professionals that lead to hospital admissions, emergency department visits, or death among adult patients (Khalil 2017).

Direct involvement of patients or their representatives in decision-making processes is seen both as an ethical imperative, and as a promising approach for quality improvement (Richards 2013). Interventions to promote shared decision-making (Légaré 2014) and patient-centred care (Dwamena 2012), including patient-mediated interventions, have been reviewed elsewhere. Also, the effectiveness of the use of decision aids among people facing treatment or screening decisions has been reviewed elsewhere (Stacey 2017).

The focus of the Stacey 2017 Cochrane review was on people’s decision-making processes, behaviour and health, and on outcomes related to health care system cost, use. The studies included in this decision aids review most likely did not address outcomes directly related to changing professional practice and would therefore not be eligible for inclusion in our review.

In this review we focus specifically on the effects of using patient involvement as a means to improving healthcare professionals’ performance. This can be done through interactions with patients, or information provided by or to patients. Examples of such interventions include:

- patient-reported health information where patients provide information about their own health, concerns, or needs before a clinical encounter;
- patient information where patients are informed about recommended care;
- patient education/training/counselling to increase patients’ knowledge about their condition;
- patient decision aids to ensure that the choices about treatment and management reflect recommended care and the patients’ values and preferences;
- patient feedback about clinical practice;
- patients being members of committees or boards of healthcare organisations;
- patient-led training or education of healthcare professionals.

We have used adherence to clinical practice guidelines and recommendations as a measure for quality of professional practice, as is commonly done, for example in Cochrane reviews of interventions to improve healthcare worker performance (Arditi 2017; Flodgren 2011a; Flodgren 2011b; Flodgren 2016; Forsetlund 2009; Giguère 2012; O’Brien 2007; Tsourtziou Brown 2016). It is worth noting that adherence to guidelines is not necessarily what a patient wants. A patient-mediated intervention could therefore improve professional practice without improving shared decision-making, and vice versa. Still, it seems reasonable to assume that most recommended clinical practices are in the best interest of the patient, and therefore also in line with the care most patients would want. The importance of patient involvement at all levels of healthcare services is widely recognised. Patients are, in general, positive to engaging in improving the quality of the care they receive (Schwappach 2010a). Also, patient information materials devel-
oped in collaboration with patients is probably more relevant, readable, understandable, and effective in improving knowledge among patients (Nilsen 2006). On the other hand, concerns have been raised about how patient involvement can affect patients’ trust in healthcare professionals and their experience of receiving healthcare (Hrisos 2013; Luszczynska 2007; McGunkin 2006). In addition, patients’ comfort level with active involvement may vary considerably, as some might feel that they can appear rude or disrespectful and that this may upset the healthcare professional and, consequently, might compromise their healthcare (Hrisos 2013). Patients may also find it hard to overcome distrust if the independence, agency, or expertise of healthcare professionals is questioned (Plomp 2010).

The patient’s socioeconomic status has been shown to correlate with the degree of involvement in treatment decisions (Willems 2005). Patients from higher social classes may get more information from their healthcare professionals because they often communicate more actively (they ask more questions and are more opinionated) and show more affective expressiveness (Willems 2005).

Most healthcare professionals, like patients, welcome patient involvement to improve healthcare safety (Davis 2012a; Davis 2012b; Hrisos 2013; Schwappach 2010b; Schwappach 2011; Schwappach 2013). When patients question or challenge healthcare professionals’ practice, however, the healthcare professionals’ morale and professional integrity may suffer negative consequences (Hrisos 2013; Schwappach 2010b). Thus, in some situations or cases, the unwanted consequences of patient-mediated interventions may negatively affect both the patient and the healthcare professional and, thus, the patient-healthcare professional relationship.

To avoid tensions between healthcare professionals and patients, a conceptual common ground or consensus on how to set treatment and management goals has been recommended (Sugavanam 2013). Collaboration and communication are important factors and communication in the form of discussions may also lead to more reciprocal, trustful relationships and more open information exchanges (Skirbekk 2011).

How the intervention might work

Despite being regarded as a promising approach for improving healthcare systems and and being the focus of research, the theoretical foundation for patient-mediated interventions seems meagre. Very few, if any, of the studies to evaluate the effectiveness of such interventions have reported use of theory in the development and design of the intervention (Gagliardi 2016; Ng 2017). Still, if healthcare professionals are well-informed about recommended clinical practices through patients or patients’ representatives, or if patients are empowered to ask for appropriate health care, it seems reasonable to believe that this can influence professional practice. Table 1 shows examples of patient-mediated interventions, how they might influence healthcare workers’ behaviour, and possible adverse effects. In Figure 1, we present a summary of various types of patient-mediated interventions and indicate two mechanisms through which they can improve patient outcomes: directly, and indirectly through improving the care provided by health professionals. This review focuses on the latter mechanism.
**Why it is important to do this review**

Although many systematic reviews exist that have assessed the effect of different patient involvement or patient-directed interventions, these have mainly focused on patient outcomes, such as satisfaction, well-being, and health. For example, there are series of Cochrane reviews on patient education/self-management programs for various conditions, including musculoskeletal-related conditions (Kroon 2014; Parreira 2017; Poquet 2016), lung-related conditions (Kelly 2018; Lenferink 2017; McCallum 2017; Peytremann-Bridevaux 2015; Zwerink 2014), stroke (Fryer 2016), heart-related conditions (Anderson 2017; Clarkesmith 2017), diabetes type 2 (Attridge 2014; McBain 2016), and cancer-related conditions (Bennett 2016). The purpose of our review, however, is to assess the effect patients can have on healthcare professionals’ performance. Similarly, there are Cochrane reviews on interventions to promote shared decision-making (Légaré 2014) and a patient-centred approach (Dwamena 2012), but these have not focused on the effects on professional practice, i.e. adherence to clinical practice guidelines or recommendations.

Previous systematic reviews have covered patient-mediated interventions as one of a wide range of interventions aimed at improving professional practice (Davis 1995; Grimshaw 2004; Oxman 1995). Some studies have found mixed effects on professional practice for patient-mediated interventions (Davis 1995; Oxman 1995), while others have reported moderate to large effects (Grimshaw 2004). The certainty of the evidence in these systematic reviews varies, but is generally low, making it impossible to draw firm conclusions about the effectiveness of these interventions. It is important to do this review as there are, to our knowledge, no recently updated systematic reviews that have assessed the effectiveness of patient-mediated interventions on healthcare professionals’ practice.

**OBJECTIVES**

To assess the effects of patient-mediated interventions on health-
care professionals’ clinical performance (adherence to clinical practice guidelines or recommendations).

METHODS

Criteria for considering studies for this review

Types of studies

We included randomised and cluster-randomised studies comparing a patient-mediated intervention to no intervention, usual care or other interventions to improve professional practice.

We included full-text studies, conference abstracts, and unpublished data.

Types of participants

We included practicing healthcare professionals and those in postgraduate training responsible for patient care. We excluded undergraduate students or non-professional (lay) healthcare workers.

Types of interventions

Types of interventions included

Interventions aimed at changing the performance of healthcare professionals through interactions with patients, or information provided by or to patients, including:

- patient-reported health information where patients provide information about their own health, concerns, or needs before a clinical encounter;
- patient information where patients are informed about recommended care;
- patient education/training/counselling to increase patients’ knowledge about their condition;
- patient feedback about clinical practice;
- patient decision aids to ensure that the choices about treatment and management reflect recommended care and the patients’ values and preferences;
- patients being members of committees or boards;
- patient-led training or education of healthcare professionals.

See Table 1 for more detailed information and examples.

We excluded studies where patient-mediated intervention was a small component in a multi-component package. We also excluded studies that did not include authentic patients (such as studies including standardised or simulated patients).

Types of comparisons included

We included studies where patient-mediated interventions were compared with common practice/usual care, or any other intervention to improve professional practice (including comparisons of different types of patient-mediated interventions).

Types of outcome measures

Primary outcomes

Adherence to recommended clinical practice or clinical practice guidelines by healthcare professionals.

Secondary outcomes

We only included studies that reported relevant primary outcomes. Thus, we extracted secondary outcomes from studies that also reported on adherence to recommended clinical practice or clinical practice guidelines.

- Patient outcomes
  - health outcomes
  - satisfaction with the care they receive
  - acceptance, confidence in, or satisfaction with the intervention
  - experiences/perceptions of healthcare professionals’ acceptance, confidence in or satisfaction with the intervention
- Healthcare professional outcomes
  - satisfaction with the care they provide
  - acceptance, confidence in or satisfaction with the intervention

We also included data on resource use, adverse events and issues of equity in the included studies.

Search methods for identification of studies

Electronic searches

We searched the following electronic databases for primary studies without any language or time limits.

- The Cochrane Central Register of Controlled Trials (CENTRAL), part of the Cochrane Library (www.cochranelibrary.com) (searched March 10, 2017)
- MEDLINE and Epub Ahead of Print, In-Process & Other Non-Indexed Citations and Daily 1946 to August 24, 2018, Ovid (searched August 28, 2018 with time limit up to March 10, 2018)

We tested whether or not to search Embase, using the phrase ‘patient mediated’ in title and abstract. We screened all records that
were unique to Embase, found none to be eligible and therefore omitted Embase from our search. See Appendix 1 for all strategies used, including the MEDLINE strategy, which was peer reviewed using the Peer Review of Electronic Search Strategies (PRESS) checklist (Sampson 2008).

**Searching other resources**

**Grey literature** (searched October 2017)
- Open Grey (www.opengrey.eu)
- Grey Literature Report (www.greylit.org)
- Google Scholar (scholar.google.com)

**Trial registries** (searched September 2017)
- International Clinical Trials Registry Platform (ICTRP), World Health Organization (WHO) (www.who.int/ictrp)
- ClinicalTrials.gov, US National Institutes of Health (NIH) (clinicaltrials.gov)

We also:
- screened the reference lists of all included studies for relevant studies;
- conducted cited reference searches for all included studies using Web of Science, Clarivate Analytics (searched October 2017).

An Information Specialist (MJ) and a review author (MSF) carried out the searches.

**Data collection and analysis**

**Selection of studies**

Two review authors (MSF and TKD) screened titles and abstracts independently to assess which studies met the inclusion criteria. We retrieved full-text copies of all papers that were potentially relevant, including those where the description of the population, intervention, comparison or outcomes was insufficient in the abstract to make a decision about inclusion. Review authors MSF and TKD independently assessed the full-text copies of the papers for relevance. We resolved any disagreements by discussion and consensus with a third review author (AF). We kept a log of the selection process to complete a PRISMA flow diagram (Moher 2009) using Covidence (Covidence) (see Figure 2). We described studies that initially appeared to meet the inclusion criteria but later were excluded, including the reasons for exclusion, in the Characteristics of included studies table.
Figure 2. Study flow diagram.

11,233 records identified through database searching

12,447 records screened

12,307 records excluded

115 full-text articles excluded, with reasons:

- 66 Outcome
- 42 Intervention or comparison
- 11 Study design
- 6 carried out of study (outcome is likely to be confounded by patients' attendance rate)

140 full-text articles assessed for eligibility

25 studies included in qualitative synthesis

20 of 25 studies included in quantitative synthesis (meta-analysis) for our primary outcome
Data extraction and management

Review authors MSF and TKD independently extracted data from each included study using a modified version of the EPOC Data Collection Checklist (EPOC 2017a). We resolved any disagreements by discussion and by consensus. When needed, a third review author (AF) was consulted. Missing or unclear data from a published study were marked clearly on the data collection form. Missing or unclear data were sought from the corresponding author of a published paper.

Assessment of risk of bias in included studies

Review authors MSF and TKD independently assessed the risk of bias in accordance with the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011), and in line with the Cochrane Effective Practice and Organisation of Care Group suggested risk of bias criteria (EPOC 2017b). We resolved any discrepancies through discussion.

We assessed the risk of bias according to the following domains:
- random sequence generation;
- allocation concealment;
- blinding of participants and personnel;
- blinding of outcome assessment;
- incomplete outcome data;
- selective outcome reporting;
- other biases (for cluster-randomised studies, we judged five additional sources of potential biases under “other biases”).

We judged each potential source of bias as high, low, or unclear and provided a quote from the study report together with a justification for our judgement in the ‘Risk of bias’ table.

Assessment of bias in conducting the systematic review

We conducted the review according to the published protocol and report any deviations from it in the Differences between protocol and review section of the systematic review.

Measures of treatment effect

For the dichotomous outcomes, we analysed data based on the number of events and the number of people or cases assessed in the intervention and comparison groups. We used these to calculate the risk ratio (RR) with 95% confidence interval (CI). For continuous outcomes, we analysed the data based on the mean, standard deviation (SD) and number of people assessed for both the intervention and comparison groups to calculate mean difference (MD) and 95% CI.

All relevant outcomes reported in the studies were collected along with data on how they were measured (self-report, medical record, other objective primary or secondary outcome). For all relevant primary and secondary outcomes, we extracted the intervention effect estimates with relevant CIs, and the method of statistical analysis used to calculate it, as reported by the authors of the study. We extracted data from all time points and categorised them into one of three follow-up time intervals (0 to 3 months, more than 3 months to 12 months, more than 12 months). Studies reporting one outcome in multiple follow-up intervals were only reported once in our meta-analyses, with the longest follow-up. Also, if a study reported multiple data within one interval, we used the data with the longest follow-up within that interval.

When the same study reported more than one relevant primary outcome (adherence outcome), we used the primary outcome as defined by the study authors. If a primary outcome was not clearly defined or multiple outcomes were defined as primary or secondary outcomes, we calculated and used the median value from all relevant primary outcomes. When calculating the median from even numbers of outcomes, we chose the outcome with reporting from the most participants. In cases where the number of participants contributing to the outcome was the same, we randomly selected the outcome (flipping coin).

Unit of analysis issues

We found eligible studies with cluster designs (studies in which the unit of allocation is not a person, but a group of people for instance in a clinic). Studies in which comparisons are allocated as groups of people should account for clustering in their analysis. Standard statistical methods assume independence of observation, and for cluster-design studies the use of these will generally result in artificially small P values and overly narrow CIs for the effect estimates (Ukoumunne 1999), if analysed at the individual level rather than at the cluster level.

We re-analysed studies with potential unit of analysis errors by using the information on the size number of clusters and the value of the intra-cluster correlation coefficient (ICC). If no ICC was reported, we used the median ICC value from similar studies found in the University of Edinburgh’s Database of ICCs (ABDN 2015). We used the following formula, as suggested by Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011): n patients / (1 + ICC (average cluster size -1)).

Dealing with missing data

We attempted to contact study authors in order to verify key study characteristics and to obtain missing numerical outcome data where possible. In cases where this was unsuccessful, we have
reported the data as ‘not reported’ and have not attempted to impute the missing values. The potential impact of the missing data is explored in the ‘Assessment of risk of bias’ section of the review.

Assessment of heterogeneity

By examining study populations, interventions and outcomes, we considered if the studies were similar enough to be pooled in a meta-analysis. We assessed the degree of statistical heterogeneity by visual examination of the scatter of effect estimates on forest plots and by using the Chi$^2$ and I$^2$ statistics (Higgins 2003).

Assessment of reporting biases

The tendency for inconclusive results to remain unpublished may impact the findings of a systematic review. We attempted to obtain study protocols to assess selective outcome reporting. Another important factor that might introduce biases is the small-study effects. We planned to use funnel plots to assess small-study effects for 10 or more studies investigating a particular outcome according to Egger 1997 (for continuous outcomes) and Harbord 2006 (for dichotomous outcomes). A funnel plot was created for the patient information comparison which had 12 studies in the meta-analysis Figure 3. Even though we did not find clear evidence for a publication bias, we cannot rule out the possibility. Also, we failed to find more studies with few participants and negative effect estimates, and we should therefore be cautious when we interpret that we have little to indicate a potential publication bias in our result.

Figure 3. Funnel plot of comparison: 2 Patient information interventions versus comparisons, outcome: 2.1 Adherence to recommended practice.

Data synthesis

We grouped patient-mediated interventions according to the six categories listed under Types of interventions, and categorised the interventions of the included studies accordingly. We then prepared tables summarising the findings of studies for each type of relevant primary and secondary outcome.

We prepared separate meta-analyses for each type of intervention
and visualised the different types of comparisons in the forest plot. We carried out the meta-analyses by using Review Manager 5 (RevMan 2014). We used random-effects meta-analysis for combining data, as we anticipated that there may be natural heterogeneity between studies attributable to the variation across similar interventions, populations and implementation strategies. For continuous variables, we used the inverse-variance method while for dichotomous variables we used the method proposed by Mantel-Haenszel. For the included studies with three or more arms, we only extracted data from the two most relevant comparisons for our question.

**Summary of findings**

We summarised the findings of the different types of patient-mediated interventions for the following outcomes in ‘Summary of findings’ tables.

- Adherence to recommended clinical practice or clinical practice guidelines by healthcare professionals
- Patient health outcomes (desirable and undesirable health outcomes)
- Patients’ satisfaction with the care they receive
- Adverse events
- Resource use

Two review authors (MSF and TKD) independently assessed the certainty of the evidence (high, moderate, low, and very low) using the five GRADE considerations (study limitations, consistency of effect, imprecision, indirectness, and publication bias). We used methods and recommendations described in Section 8.5 and Chapter 12 of Higgins 2011 and the EPOC worksheets (EPOC 2017c), using GRADEpro software (GRADEpro GDT 2015). We resolved disagreements on certainty ratings by discussion and consulted a third review author (AF) when disagreement persisted. Our decisions to down- or upgrade are presented in footnotes in the tables. We used plain language statements to report these findings in the review (EPOC 2017d).

**Subgroup analysis and investigation of heterogeneity**

We assessed heterogeneity between studies by visually inspecting forest plots and, if possible, by performing subgroup analyses (see below). Since the importance of inconsistency depends on several factors, we used the guide to interpret heterogeneity as outlined in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011): 0% to 40% might not be important; 30% to 60% may represent moderate heterogeneity; 50% to 90% may represent substantial heterogeneity; and 75% to 100% would be considerable heterogeneity.

When the effect estimates varied considerably across studies of similar types of patient-mediated interventions, we explored whether the following factors could explain the observed variation.

- Direction of change required (increase current behaviour, decrease current behaviour, mix, or unclear). Hypothesis: effect on increasing a behaviour is larger than that on decreasing behaviour.
- Recipient (physician; other healthcare professionals). Hypothesis: clinical practice is more difficult to change among physicians than among non-physicians.
- Risk of bias (high; unclear; low). Hypothesis: effect sizes are smaller when risk of bias is low.
- Baseline clinical performance (continuous measure of healthcare professionals’ compliance with recommended clinical practice or clinical guidelines). Hypothesis: when baseline clinical performance is low, effect sizes are larger.

**Sensitivity analysis**

We did not perform any sensitivity analysis.

**Results of the search**

We identified a total of 12,247 records from the electronic and supplementary searches (11,003 from electronic database searching and 1244 of additional records identified through clinicaltrial.gov (1040) and ICTRP (81), Open Grey (85), Grey Literature Report (7) and Google Sholar (31)) Figure 2. Two review authors (MSF and TKD) independently screened 12,247 titles and abstracts and found 12,107 records to be irrelevant and these were directly excluded. Full-text publications were retrieved for 139 of the 140 potential relevant studies. For one study we only had information presented in an abstract (Caskey 2011). We included 25 studies (Alder 2005; Aragones 2010; Brody 1990; Caskey 2011; Christy 2013; Goldberg 2012; Herman 1995; Jacobson 1999; Kattan 2006; Kenealy 2005; Khan 2011; Kravitz 2012; Krol 2004; Leveille 2009; Mazonson 1996; McAlister 2005; McKinstry 2006; Miaskowski 2004; Mouland 1997; Nagykaldi 2012; Quinn 2008; Thiboutot 2013; Thomas 2003; Turner 1990; Wright 2012). We also identified two ongoing studies (NCT01904656; NCT02686775).

**Included studies**

The 25 included studies are described in detail in the Characteristics of included studies.
Study design

Fifteen studies were randomised at the individual level. Twelve of these studies had the patient as the unit of randomisation (Alder 2005; Christy 2013; Jacobson 1999; Kattan 2006; Khan 2011; Kravitz 2012; Leveille 2009; McKinstry 2006; Miaskowski 2004; Mouland 1997; Quinn 2008; Thomas 2003), and three had the healthcare professional as the unit (Aragones 2010; Goldberg 2012; Turner 1990). Ten studies were cluster-randomised studies. Among the cluster-randomised studies, five had the healthcare professional as the unit of randomisation (Caskey 2011; Kenealy 2005; Krol 2004; Mazonson 1996; Thiboutot 2013), and five had the healthcare practice as the unit of randomisation (Brody 1990; Herman 1995; McAlister 2005; Nagykaldi 2012; Wright 2012). Cluster-randomisation may lead to misleading findings unless the results are adjusted for clustering effects. The idea is to reduce the size of each trial to its 'effective sample size' to prevent artificially small P values. To prevent this 'unit of analysis error' caused by clustering, we re-analysed the studies included in our meta-analyses by using the information on the number of clusters and the assumed value of the intra-cluster correlation coefficient (ICC). We have analysed the impact of clustering effects among all the ten cluster-randomised studies. For the five studies in which healthcare professionals were the unit of randomisation (Caskey 2011; Kenealy 2005; Krol 2004; Mazonson 1996; Thiboutot 2013), the median ICC among similar studies for our primary outcome was 0.000 (95% CI; 0, 0.142) according to the University of Edinburgh’s Database of ICCs (ABDN 2015). The effective sample sizes of these studies were thus the same as reported by the study authors. The effective sample size for the five studies in which the healthcare practice was the unit of randomisation (Brody 1990; Herman 1995; McAlister 2005; Nagykaldi 2012; Wright 2012), the median ICC among similar studies for our primary outcome in the University of Edinburgh’s Database of ICCs (ABDN 2015) was 0.076 (95% CI, 0, 0.219). We did not attempt to re-analyse studies that were not pooled in a meta-analysis (Brody 1990; Nagykaldi 2012). The effective total sample sizes for the three cluster-randomised studies included in our meta-analyses (Herman 1995; McAlister 2005; Wright 2012) were calculated and are listed in Table 2.

Most of the studies had two comparison arms, except for Brody 1990, Herman 1995 and Thomas 2003, which had three arms, and Alder 2005 and Kenealy 2005, which had four arms. We selected and analysed data from two relevant arms per study (see Characteristics of included studies for description).

Population/participants

Patients

The total number of patients included in the studies of this review was 12,268 (the total number of patients would be 16,700 if we had included all comparison arms in the studies). The included sample size varied from 40 participants (Alder 2005) to 3189 (Kenealy 2005). The number of patients contributing to our meta-analyses for the primary outcome is 8749. Ten studies were on preventive care with a general patient population (Caskey 2011; Nagykaldi 2012; Turner 1990; Wright 2012) or an ‘at risk’ patient population (Aragones 2010; Christy 2013; Herman 1995; Jacobson 1999; Kenealy 2005; Thomas 2003), of which all except one study (Jacobson 1999) defined risk based on an age-threshold, often 50 years or older. One study, which was on vaccination, defined ‘at risk’ as having a chronic condition. The preventive service provided in the studies included cancer screening (Aragones 2010; Christy 2013; Herman 1995), diabetes screening (Kenealy 2005), vaccination (Caskey 2011; Jacobson 1999; Nagykaldi 2012; Thomas 2003), and both vaccination and cancer screening (Turner 1990; Wright 2012). Fifteen studies were on identification, treatment or management of patients with certain conditions such as mental health problems (Brody 1990; Mazonson 1996; Mouland 1997), asthma (Goldberg 2012; Kattan 2006), diabetes (Khan 2011; Quinn 2008), cancer (Kravitz 2012; Miaskowski 2004), hypertension (McKinstry 2006; Thiboutot 2013), heart-related disease (McAlister 2005), dyspepsia (Krol 2004), and musculoskeletal pain, depression and mobility difficulty (Leveille 2009), and upper respiratory tract symptoms (Alder 2005).

Most studies included adult patients except for three studies (Alder 2005; Goldberg 2012; Kattan 2006) in which the children’s mean age varied between three years (Alder 2005) and seven/eight years (Goldberg 2012; Kattan 2006). The total number of children included in our analyses was 1054. In two of these three studies the children were mostly female (Alder 2005; Goldberg 2012). Among the 22 studies with adult patients, 18 studies had a mean patient age of 50 years or more. The mean patient age was below 50 years in three studies (Mazonson 1996; Quinn 2008; Wright 2012), and age was not reported in one study (Caskey 2011). In seventeen of the 22 studies with adult patients over fifty per cent of participants were women. One study recruited only women (Herman 1995), one study did not report on gender (Caskey 2011), and three studies included mostly men (Kenealy 2005; Khan 2011; McAlister 2005). Among the 25 included studies one study recruited only Latino immigrants (Aragones 2010), and another study only African-Americans (Christy 2013).

Healthcare professionals

All studies involved physicians, but in five studies nurses and physician assistants were also included (Jacobson 1999; Kattan 2006; McKinstry 2006; Nagykaldi 2012; Thomas 2003). The number of healthcare professionals included in the studies was not consistently reported, but for the studies where this information was available the total number ranged from 8 to 167 (see Characteristics of included studies for further details).
Interventions and comparisons

Interventions

We categorised six studies as patient-reported health information interventions (Brody 1990; Goldberg 2012; Kattan 2006; Kenealy 2005; Mazonson 1996; Quinn 2008). We categorised 13 studies as patient-information interventions. These included written or electronic reminders, prompts, handouts, posters etc. (Caskey 2011; Herman 1995; Jacobson 1999; Krol 2004; McKinstry 2006; Mouland 1997; Turner 1990; Wright 2012) or video or web-based information (Aragones 2010; Christy 2013; Nagykaldi 2012; Thomas 2003). Five studies were patient-education interventions (Alder 2005; Khan 2011; Kravitz 2012; Miaskowski 2004; Thiboutot 2013). These varied greatly in content from electronic based education or training (Khan 2011; Thiboutot 2013), to in-person communication or coaching interventions (Alder 2005; Kravitz 2012), to a multi session nurse-led patient-education intervention (Miaskowski 2004). The remaining study was about patient decision aids (McAlister 2005).

We did not identify any studies fulfilling our inclusion criteria that involved other patient-mediated interventions such as patient feedback about clinical practice, patients being members of committees or boards, or patient-led training or education of healthcare professionals.

Fourteen studies delivered the intervention at the practice site (Alder 2005; Aragones 2010; Brody 1990; Caskey 2011; Christy 2013; Goldberg 2012; Herman 1995; Jacobson 1999; Kenealy 2005; Khan 2011; Kravitz 2012; Mazonson 1996; Thomas 2003; Turner 1990). The remaining studies delivered the intervention outside the practice, including in the patient’s home, in person (Miaskowski 2004), by telephone (Kattan 2006), electronically (e-mail or web portal) (Leveille 2009; Nagykaldi 2012; Quinn 2008; Thiboutot 2013; Wright 2012), or by post (Krol 2004; McAlister 2005; McKinstry 2006; Mouland 1997). Among the studies where the intervention was delivered outside the practice, four studies had a “one-time delivery” of the intervention (Krol 2004; McAlister 2005; McKinstry 2006; Mouland 1997) and seven studies had continuous intervention delivery over three months or less (Kattan 2006; Leveille 2009; Miaskowski 2004; Wright 2012), or over a year (Nagykaldi 2012; Quinn 2008; Thiboutot 2013).

Comparisons

The comparisons were categorised as “no intervention” in 11 studies (Brody 1990; Caskey 2011; Goldberg 2012; Herman 1995; Kattan 2006; Kenealy 2005; Mazonson 1996; Mouland 1997; Nagykaldi 2012; Quinn 2008; Turner 1990) and “usual care” in 14 studies (Alder 2005; Aragones 2010; Christy 2013; Jacobson 1999; Khan 2011; Kravitz 2012; Krol 2004; Leveille 2009; McAlister 2005; McKinstry 2006; Miaskowski 2004; Thiboutot 2013; Thomas 2003; Wright 2012). Among the 11 studies within the “no intervention” comparison category, five studies had a “pure” “no intervention” comparison (Brody 1990; Goldberg 2012; Kattan 2006; Mazonson 1996; Nagykaldi 2012), while in the remaining six, both groups received a non-patient-mediated intervention component (Caskey 2011; Herman 1995; Kenealy 2005; Mazonson 1996; Quinn 2008; Turner 1990). These non-patient-mediated intervention components were typically information or reminders given to healthcare professionals in both groups. Among the 14 studies within the “usual care” comparison category, two studies were described as having a “usual care” comparison without further description (Aragones 2010; Krol 2004), six studies used a placebo-like usual care-comparison, where the comparison group typically received patient information not related to the health condition(s) being studied (Alder 2005; Jacobson 1999; Leveille 2009; Thiboutot 2013; Thomas 2003; Wright 2012) and six studies used a patient information-like usual care-comparison, where the comparison group was given minimal patient information about the health condition being studied as part of usual care (Christy 2013; Khan 2011; Kravitz 2012; McAlister 2005; McKinstry 2006; Miaskowski 2004). This was typically untailored or standard information brochures about the health condition being studied and could be given to both the comparison group and patient-mediated intervention group (Kravitz 2012; McAlister 2005; McKinstry 2006) or to the comparison group only (Christy 2013; Khan 2011; Miaskowski 2004).

Outcomes

Primary outcomes

The primary outcome, adherence to recommended clinical practice, was reported in all 25 studies. The outcomes we defined as primary were defined as primary outcomes in eight studies (Caskey 2011; Goldberg 2012; Jacobson 1999; Kenealy 2005; Krol 2004; Leveille 2009; Mazonson 1996; Wright 2012), and secondary outcomes in eight studies (Aragones 2010; Christy 2013; McAlister 2005; McKinstry 2006; Miaskowski 2004; Quinn 2008; Thiboutot 2013; Thomas 2003). The outcomes were not categorised into primary and secondary outcomes in nine studies (Alder 2005; Brody 1990; Herman 1995; Kattan 2006; Khan 2011; Kravitz 2012; Mouland 1997; Nagykaldi 2012; Turner 1990). All studies except for one (Brody 1990), reported the primary outcome in a dichotomous way.
Secondary outcomes

Secondary outcomes that matched our inclusion criteria were reported in 12 of the 25 included studies (Alder 2005; Brody 1990; Herman 1995; Kattan 2006; Khan 2011; Kravitz 2012; Krol 2004; Leveille 2009; McKinstry 2006; Miaskowski 2004; Quinn 2008; Thiboutot 2013).

Eight of the 12 studies reported patient health outcomes (Brody 1990; Khan 2011; Kravitz 2012; Krol 2004; Leveille 2009; McKinstry 2006; Miaskowski 2004; Thiboutot 2013). Patient satisfaction with the care they received was reported in four studies (Alder 2005; Brody 1990; Leveille 2009; Quinn 2008), and resource use was reported in one study (Kattan 2006).

None of the included studies reported on:
- patients’ acceptance, confidence in, or satisfaction with the intervention;
- patients’ experiences / perceptions of healthcare professionals acceptance, confidence in or satisfaction with the intervention;
- healthcare professionals’ satisfaction with the care they provide;
- healthcare professionals’ acceptance, confidence in or satisfaction with the intervention;
- adverse events;
- equity.

For all included outcomes, we narratively report effect estimates as reported by the authors of the study (Table 2; Table 3), and also report how these data were collected (self-report or medical record) (Characteristics of included studies).

When the same study reported more than one relevant primary outcome (adherence outcome), we used the primary outcome as defined by the study authors. If a primary outcome was not clearly defined (Herman 1995; Khan 2011; Turner 1990), or multiple outcomes were defined as primary (Goldberg 2012; Wright 2012) or secondary outcomes (McKinstry 2006; Thiboutot 2013), we calculated and used the median value from all relevant primary outcomes. When calculating the median from even numbers of outcomes (Goldberg 2012; Herman 1995; Khan 2011; McKinstry 2006; Turner 1990; Wright 2012), we chose the outcome with reporting from the most participants (Herman 1995; McKinstry 2006; Turner 1990; Wright 2012). In cases where the number of participants contributing to the outcome was the same, we randomly selected the outcome (flip of a coin) (Goldberg 2012; Khan 2011).

The time points at which our primary outcomes were measured was within the 0-3 months interval in most of the studies except from four studies (Krol 2004; McAlister 2005; McKinstry 2006; Mouland 1997), in which our primary outcomes were measured within the 3-12 months interval.

Excluded studies

We excluded 115 studies, see Characteristics of excluded studies. Fifty-six studies were excluded on the basis of outcomes and 42 studies on the basis of interventions or comparisons. The remaining studies were excluded on the basis of study design (11 studies) and the way the studies were carried out (no guarantee that a clinical encounter took place and thus the outcome is likely to be confounded by patients’ attendance rates) (six studies).

Risk of bias in included studies

The judgments for the risk of bias from the 25 included studies are summarised in Figure 4 and Figure 5. We found 10 studies with adequate randomisation generation (Goldberg 2012; Jacobson 1999; Kattan 2006; Kenealy 2005; Khan 2011; Kravitz 2012; McAlister 2005; McKinstry 2006; Mouland 1997; Thiboutot 2013). Two studies had high risk of allocation bias due to lack of a random sequence generation (Thomas 2003; Turner 1990). Thirteen studies had unclear reporting of the randomisation (Alder 2005; Aragones 2010; Brody 1990; Caskey 2013; Herman 1995; Krol 2004; Leveille 2009; Mazonson 1996; Miaskowski 2004; Nagykaldi 2012; Quinn 2008; Wright 2012).
Figure 4. 'Risk of bias' graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.
Figure 5. 'Risk of bias' summary: review authors' judgements about each risk of bias item for each included study.

Allocation

Random sequence generation

Allocation concealment
We judged allocation concealment to be adequate in four studies (Kattan 2006; Kenealy 2005; Kravitz 2012; McAlister 2005). Twenty studies had unclear reporting of allocation concealment (Alder 2005; Aragones 2010; Brody 1990; Caskey 2011; Christy 2013; Goldberg 2012; Herman 1995; Jacobson 1999; Khan 2011; Krol 2004; Leveille 2009; Mazonson 1996; McKinstry 2006; Miaskowski 2004; Mouland 1997; Nagykaldi 2012; Quinn 2008; Thiboutot 2013; Turner 1990; Wright 2012) and one study had high risk of bias due to lack of adequate allocation concealment.

Blinding
We judged participants and personnel to be blinded in four studies (Jacobson 1999; Kravitz 2012; Miaskowski 2004; Thiboutot 2013) and not blinded in 11 studies (Aragones 2010; Kattan 2006; Kenealy 2005; Khan 2011; Mazonson 1996; McAlister 2005; McKinstry 2006; Mouland 1997; Nagykaldi 2012; Quinn 2008; Thomas 2003). We judged the remaining 10 studies (Alder 2005; Brody 1990; Caskey 2011; Christy 2013; Goldberg 2012; Herman 1995; Krol 2004; Leveille 2009; Turner 1990; Wright 2012) to have unclear risk of bias because these studies did not sufficiently describe participant and personnel blinding.

We judged outcome assessors to be blinded in eight studies (Aragones 2010; Brody 1990; Kattan 2006; Kenealy 2005; Kravitz 2012; McAlister 2005; McKinstry 2006; Thiboutot 2013) and not blinded in two studies (Jacobson 1999; Quinn 2008). We judged the remaining 15 studies (Alder 2005; Caskey 2011; Christy 2013; Goldberg 2012; Herman 1995; Khan 2011; Krol 2004; Leveille 2009; Mazonson 1996; Miaskowski 2004; Mouland 1997; Nagykaldi 2012; Thomas 2003; Turner 1990; Wright 2012) to have unclear risk of bias because these studies did not sufficiently describe blinding of outcome assessors.

Incomplete outcome data
We found no indication of incomplete outcome data in most of the studies (Alder 2005; Aragones 2010; Christy 2013; Goldberg 2012; Kattan 2006; Kenealy 2005; Khan 2011; Kravitz 2012; Krol 2004; Leveille 2009; Mazonson 1996; McAlister 2005; McKinstry 2006; Miaskowski 2004; Mouland 1997; Quinn 2008; Thiboutot 2013; Thomas 2003; Turner 1990; Wright 2012). We judged one study (Nagykaldi 2012) to have high risk of bias and four studies (Brody 1990; Caskey 2011; Herman 1995; Jacobson 1999;) to have unclear risk of attrition bias.

Selective reporting
We could not decide if there was a risk of selective reporting in more than half of the studies (Alder 2005; Brody 1990; Caskey 2011; Jacobson 1999; Kattan 2006; Kenealy 2005; Khan 2011; Krol 2004; Mazonson 1996; Mouland 1997; Quinn 2008; Thomas 2003; Turner 1990; Wright 2012). We judged one study (Herman 1995) to have high risk of bias and 10 to have low risk of bias (Aragones 2010; Christy 2013; Goldberg 2012; Kravitz 2012; Leveille 2009; McAlister 2005; McKinstry 2006; Miaskowski 2004; Nagykaldi 2012; Thiboutot 2013).

Other potential sources of bias
We inspected all the studies for potential bias due to baseline imbalance in key characteristics and baseline outcome imbalance. We found high risk of baseline imbalance in key characteristics in two studies (Alder 2005; Wright 2012). We judged 11 studies to have low risk of bias (Aragones 2010; Brody 1990; Christy 2013; Kenealy 2005; Khan 2011; Leveille 2009; Mazonson 1996; McAlister 2005; McKinstry 2006; Miaskowski 2004; Nagykaldi 2012) and 12 to have unclear risk of baseline imbalance (Caskey 2011; Goldberg 2012; Herman 1995; Jacobson 1999; Kattan 2006; Kravitz 2012; Krol 2004; Mouland 1997; Quinn 2008; Thiboutot 2013; Thomas 2003; Turner 1990). For baseline outcome imbalance, five out of 25 had low risk (Khan 2011; McAlister 2005; McKinstry 2006; Miaskowski 2004; Mouland 1997), while the remaining 20 had unclear risk. Only two (McAlister 2005; McKinstry 2006) of the 25 studies reported the relevant primary outcome at baseline, one reported one of the primary outcomes, but not the one used for the meta-analysis (Mouland 1997) while three studies reported secondary outcomes at baseline (Khan 2011; McKinstry 2006; Miaskowski 2004).

Ten studies were cluster-randomised studies (Brody 1990; Caskey 2011; Herman 1995; Kenealy 2005; Krol 2004; Mazonson 1996; McAlister 2005; Nagykaldi 2012; Thiboutot 2013; Wright 2012) and we searched for information about five additional sources of potential biases. There was high risk of bias in three of the ten
studies (Nagykaldi 2012; Thiboutot 2013; Wright 2012) and low risk of bias in six studies (Brody 1990; Herman 1995; Kenealy 2005; Krol 2004; Mazonson 1996; McAlister 2005). The remaining study was judged to be unclear (Caskey 2011). The rationale for all the judgements are presented in the table of Risk of bias in included studies.

Among the 15 individual randomised studies (Alder 2005; Aragones 2010; Christy 2013; Goldberg 2012; Jacobson 1999; Kattan 2006; Khan 2011; Kravitz 2012; Leveille 2009; McKinstry 2006; Miaskowski 2004; Mouland 1997; Quinn 2008; Thomas 2003; Turner 1990) we found no indication of other risk of bias in five of these studies (Aragones 2010; Kravitz 2012; Leveille 2009; McKinstry 2006; Miaskowski 2004,) but the remaining ten studies were unclear (Alder 2005; Christy 2013; Goldberg 2012; Jacobson 1999; Kattan 2006; Khan 2011; Mouland 1997; Quinn 2008; Thomas 2003; Turner 1990).

Thus all in all, we found no indication of other risk of bias in 11 studies (Aragones 2010; Brody 1990; Herman 1995; Kenealy 2005; Kravitz 2012; Krol 2004; Leveille 2009; Mazonson 1996; McAlister 2005; McKinstry 2006; Miaskowski 2004), high risk of bias in three studies (Nagykaldi 2012; Thiboutot 2013; Wright 2012), and unclear risk in eleven studies (Alder 2005; Caskey 2011; Christy 2013; Goldberg 2012; Jacobson 1999; Kattan 2006; Khan 2011; Mouland 1997; Quinn 2008; Thomas 2003; Turner 1990).

Effects of interventions

See: Summary of findings for the main comparison Patient-reported health information interventions versus comparisons to improve professional performance; Summary of findings 2 Patient information interventions versus comparisons to improve professional performance; Summary of findings 3 Patient education interventions versus comparisons to improve professional performance; Summary of findings 4 Patient decision aid interventions versus comparisons to improve professional performance

See Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3, and Summary of findings 4 for patient-mediated interventions versus comparisons. The comparisons were categorised as "no intervention" and "usual care" (see Types of interventions) and these comparisons were merged for analysis and reporting because they appeared quite similar.

Adherence to recommended clinical practice was our primary outcome. We included 20 studies and a total of 8749 patients in our meta-analyses. Our meta-analyses show that patient-reported health information interventions and patient education interventions probably improve professional performance and the two other types of patient-mediated interventions may improve professional performance (patient information) or may have little or no impact (patient decision aids) (Analysis 1.1; Analysis 2.1; Analysis 3.1; Analysis 4.1).

Patient-reported health information interventions

Primary outcome

Adherence to recommended clinical practice

Six studies about patient-reported health information interventions reported on our primary outcome (Brody 1990; Goldberg 2012; Kattan 2006; Kenealy 2005; Mazonson 1996; Quinn 2008). We included four studies (Goldberg 2012; Kenealy 2005; Mazonson 1996; Quinn 2008) in our meta-analysis (Analysis 1.1). We report on two studies narratively (Table 2) due to incomplete outcome reporting (Kattan 2006) or because the outcome was reported as a continuous variable (Brody 1990). The effect estimate expressed as risk ratio (RR), is 1.59 (95% confidence interval (CI) 1.41 to 1.81; 4 studies, 3865 patients) (Analysis 1.1).

In absolute numbers: for every 100 patients consulted or treated in the patient-reported health information group there probably are 26 (95% CI 23 to 30) that are in accordance with recommended clinical practice compared to 17 per 100 in the comparison group (no intervention or usual care). We judged the certainty of the evidence as moderate. We can thus conclude that patient-reported health information interventions probably improve healthcare professionals’ adherence to recommended clinical practice compared to no intervention, usual care, or other interventions.

The two studies not included in the meta-analysis reported findings in favour of the patient-reported health information intervention (Kattan 2006) or no effect (Brody 1990) - see Table 2.

Secondary outcomes

Patient outcomes

Desirable patient health outcomes

One study (Brody 1990), reported on desirable health outcomes dichotomously (increase in control over stress) for patient-reported health information interventions. The result for this outcome is presented in Analysis 1.2. The relative effect estimate, RR, is 1.62 (95% CI 0.95 to 2.76; 1 study, 79 patients). We judged the certainty of the evidence as very low. We are thus uncertain about the effect of patient-reported health information interventions on desirable patient health outcomes because the certainty of the evidence is very low.
Undesirable patient health outcomes

None of the included studies reported on this outcome.

Patient satisfaction

One study (Quinn 2008), reported on patient satisfaction dichotomously for patient-reported health information interventions and is presented in Analysis 1.3. The relative effect estimate, RR, is 2.45 (95% CI 1.27 to 4.74; 1 study, 26 patients). We judged the certainty of the evidence as very low. We are thus uncertain about the effect of patient-reported health information interventions on the number of satisfied patients because the certainty of the evidence is very low.

Another study (Brody 1990) reported on patient satisfaction continuously for patient-reported health information interventions and is presented in Analysis 1.4. Our summary shows that the mean difference (MD) in the degree of satisfaction is 0.40 points higher (95% CI 0.12 to 0.68 higher; 1 study, 79 patients). We judged the certainty of the evidence as very low. We are thus uncertain about the effect of patient-reported health information interventions on the degree of patient satisfaction because the certainty of the evidence is very low.

Other patient outcomes

None of the included studies reported on other patient outcomes (patients’ acceptance, confidence in, or satisfaction with the intervention; patients’ experiences / perceptions of healthcare professionals acceptance, confidence in or satisfaction with the intervention).

Healthcare professional outcomes

None of the included studies reported on any healthcare professional outcomes.

Resource use

One study reported on cost-effectiveness (Kattan 2006), and is narratively presented in Table 3. The researchers in this study reported a total cost of 69.20 US $ per child per year. When this cost was added to the cost of healthcare services use for the year by intervention children and compared with the cost of healthcare service use by children in the comparison group, there was a saving of $337.00 per child in the intervention group. The researchers reported that the intervention had a 97% chance of being cost saving. We did not judge the certainty of the evidence for this outcome.

Adverse events

None of the included studies reported on this outcome.

Equity

None of the included studies reported on this outcome.

Patient information interventions

Primary outcome

Adherence to recommended clinical practice

Thirteen studies about patient information interventions (Aragones 2010; Caskey 2011; Christy 2013; Herman 1995; Jacobson 1999; Krol 2004; Leveille 2009; McKinstry 2006; Mouland 1997; Nagykaldi 2012; Thomas 2003; Turner 1990; Wright 2012) reported on our primary outcome. Eleven studies (Aragones 2010; Christy 2013; Herman 1995; Jacobson 1999; Krol 2004; Leveille 2009; McKinstry 2006; Mouland 1997; Thomas 2003; Turner 1990; Wright 2012) were included in our meta-analysis (Analysis 2.1) and two studies (Caskey 2011; Nagykaldi 2012) narratively (Table 2) due to incomplete outcome reporting. The effect estimate expressed as RR, is 1.60 (95% CI 1.20 to 2.13; 11 studies, 3502 patients) (Analysis 2.1).

In absolute numbers: for every 100 patients consulted or treated in the patient information group there may be 32 (95% CI 24 to 42) that are in accordance with recommended clinical practice compared to 20 per 100 in the comparison group (no intervention or usual care). We judged the certainty of the evidence as low. We can thus conclude that patient information interventions may improve healthcare professionals’ adherence to recommended clinical practice compared to no intervention, usual care, or other interventions.

The two studies not included in the meta-analysis (Caskey 2011; Nagykaldi 2012) reported findings in favour of the patient information intervention intervention - see Table 2.

There was statistical heterogeneity (I² = 79%) for the pooled primary outcome for patient information interventions (see Analysis 2.1). The planned subgroup analyses of explanatory factors (risk of bias, direction of change required, type of recipient, and baseline clinical performance) were carried out for two of the predetermined factors: risk of bias (see Analysis 2.2) and the direction of change required (see Analysis 2.3). Since the target group (recipients) in all the studies were physicians, type of recipient could not explain the observed statistical heterogeneity. The baseline clinical performance was generally poorly reported so we decided not to carry out a subgroup analysis for this variable either. The two subgroup analyses we carried out did not provide any explanation for the observed statistical heterogeneity.
Secondary outcomes

Patient outcomes

Desirable patient health outcomes
One study (McKinstry 2006) reported on desirable health outcomes (controlled blood pressure) for patient information interventions. The result for this outcome is presented in Analysis 2.4. The relative effect estimate, RR, is 0.99 (95% CI 0.79 to 1.24; 1 study, 261 patients). We judged the certainty of the evidence as low. We can thus conclude that there may be little or no difference in the number of people with desirable health outcomes among people in the patient information intervention group compared to those in the comparison group (usual care).

Undesirable patient health outcomes
Two studies (Krol 2004; Leveille 2009) reported on undesirable health outcomes (high dyspepsia severity or fair to poor health) for patient information interventions. The result is presented in Analysis 2.5. The relative effect estimate, RR, is 0.94 (95% CI 0.53 to 1.67; 2 studies, 246 patients). We judged the certainty of the evidence as very low. We are thus uncertain about the effect of patient information interventions on undesirable patient outcomes because the certainty of the evidence is very low.

Patient satisfaction
One study (Leveille 2009) report on patient satisfaction dichotomously for patient information interventions and is presented in Analysis 2.6. The relative effect estimate, RR, is 1.03 (95% CI 0.93 to 1.13; 1 study, 186 patients). We judged the certainty of the evidence as low. We can thus conclude that there may be little or no difference in the number of satisfied patients among those in the patient information intervention group compared to those in the comparison group (usual care).

The same study (Leveille 2009) reported on patient satisfaction continuously for patient information interventions and is presented in Analysis 2.7. Our summary shows that the in the degree of satisfaction is 0.30 points higher (95% CI 0.01 to 0.59 higher; 1 study, 186 patients) on a scale from one to ten (in which ten is best). We judged the certainty of the evidence as low. We can thus conclude that there may be little or no difference in the degree of satisfaction among patients in the patient information intervention group compared to those in the comparison group (usual care).

Other patient outcomes
None of the included studies reported on other patient outcomes (patients’ acceptance, confidence in, or satisfaction with the intervention; patients’ experiences/perceptions of healthcare professionals’ acceptance, confidence in, or satisfaction with the intervention).

Healthcare professional outcomes
None of the included studies reported on any healthcare professional outcomes.

Resource use
None of the included studies reported on this outcome.

Adverse events
None of the included studies reported on this outcome.

Equity
None of the included studies reported on this outcome.

Patient education interventions

Primary outcome

Adherence to recommended clinical practice
Five studies about patient education interventions reported on our primary outcome (Alder 2005; Khan 2011; Kravitz 2012; Miaskowski 2004; Thiboutot 2013). Four studies (Khan 2011; Kravitz 2012; Miaskowski 2004; Thiboutot 2013) were included in our meta-analysis (Analysis 3.1) and one study (Alder 2005) was reported descriptively (Table 2) due to incomplete outcome reporting. The effect estimate expressed as RR, is 1.31 (95% CI 1.12 to 1.54; 4 studies, 1029 patients) (Analysis 3.1).

In absolute numbers: for every 100 patients consulted or treated in the patient education group there may be 46 (95% CI 39 to 54) that are in accordance with recommended clinical practice compared to 35 per 100 in the comparison group (no intervention or usual care). We judged the certainty of the evidence as moderate. Thus we can conclude that patient education interventions probably improve healthcare professionals’ adherence to recommended clinical practice compared no intervention or usual care. The study not included in the meta-analysis (Alder 2005) reported findings in favour of the patient education intervention and is summarised in Table 2.
Secondary outcomes

Patient outcomes

Desirable patient health outcomes
One study (Thiboutot 2013) reported on desirable health outcomes (controlled blood pressure) for patient education interventions. The result for this outcome is presented in Analysis 3.2. The relative effect estimate, RR, is 1.09 (95% CI 0.96 to 1.23; 1 study, 500 patients). We judged the certainty of the evidence as low. We can thus conclude that patient education interventions may slightly increase the number of people with desirable health outcomes compared to usual care.

Undesirable patient health outcomes
None of the included studies reported on this outcome.

Patient satisfaction
None of the included studies reported on this outcome.

Other patient outcomes
None of the included studies reported on other patient outcomes (patients’ acceptance, confidence in, or satisfaction with the intervention; patients’ experiences/perceptions of healthcare professionals’ acceptance, confidence in or satisfaction with the intervention).

Healthcare professional outcomes
None of the included studies reported on any healthcare professional outcomes.

Resource use
None of the included studies reported on this outcome.

Adverse events
None of the included studies reported on this outcome.

Equity
None of the included studies reported on this outcome.

Patient decision aid interventions

Primary outcome

Adherence to recommended clinical practice
One study about patient decision aid interventions reported on our primary outcome (McAlister 2005). The result for this outcome is presented in Analysis 4.1. The effect estimate expressed as RR, is 0.86 (95% CI 0.65 to 1.15; 1 study, 353 patients). In absolute numbers: for every 100 patients consulted or treated in the patient education group there may be 32 (95% CI 24 to 43) that are in accordance with recommended clinical practice compared to 37 per 100 in the comparison group (usual care). We judged the certainty of the evidence as low. Thus patient decision aid interventions may make little or no difference to healthcare professionals’ adherence to recommended clinical practice compared to usual care.
### Additional Summary of Findings

#### Patient information interventions versus comparisons to improve professional performance

**Patient or population:** general patient population, “at risk” patient population and patient population with a specific condition or disease  
**Setting:** primary care (mostly)  
**Intervention:** patient information interventions  
**Comparison:** no intervention or usual care

### GRADE Working Group grades of evidence

**High certainty:** This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different** is low.

**Moderate certainty:** This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different** is moderate.

**Low certainty:** This research provides some indication of the likely effect. However, the likelihood that it will be substantially different** is high.

**Very low certainty:** This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different** is very high.

---

1. Downgraded one level because all the studies were judged to have potential risk of bias,
2. Downgraded one level for inconsistency because of statistical heterogeneity ($I^2$ is 79%)
3. Downgraded two levels for imprecision because of few events and a 95% CI that crosses the line of “no effect”
4. Downgraded one level for imprecision because of small study sample
5. Downgraded one level because we judged the study to have potential risk of bias
6. Downgraded one level for imprecision because of few events

1 The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

CI: Confidence interval; RR: Risk ratio

**GRADE Working Group grades of evidence**

**High certainty:** This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different** is low.

**Moderate certainty:** This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different** is moderate.

**Low certainty:** This research provides some indication of the likely effect. However, the likelihood that it will be substantially different** is high.

**Very low certainty:** This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different** is very high

** Substantially different = a large enough difference that it might affect a decision.

1 Downgraded one level because the study was assessed as having high risk of performance bias (no blinding of patients or healthcare professionals)

2 Downgraded one level for imprecision because of few events and because the 95% CI crosses the line of “no effect”

3 McAlister 2005
DISCUSSION

Summary of main results

We included 25 studies assessing a range of patient-mediated interventions to improve professional practice, compared to no intervention or usual care. The patient-mediated interventions in the included studies all fell within the predefined categories in the review protocol and are shown in Table 1. The interventions in the included studies were categorised as patient-reported health information, patient information, patient education, or patient decision aids and are presented as separate analyses (Analysis 1.1; Analysis 2.1; Analysis 3.1; Analysis 4.1). Most of the studies were carried out in a primary care setting, and about half of the studies focused on the identification, treatment or management of common long-term conditions (such as diabetes, asthma or depression) while the other half focused on preventive care (such as cancer screening or vaccination).

We found that patient-reported health information interventions and patient education interventions probably improve professional performance compared to no intervention or usual care (moderate certainty of the evidence). Other patient-mediated interventions, such as patient information, may also improve professional practice (low certainty of the evidence). Patient decision aids may have little or no impact on professional performance compared to usual care (low certainty of the evidence).

The impacts of these four types of patient-mediated intervention on health and satisfaction outcomes among patients varies. The effects of patient-mediated interventions on the remaining predefined secondary outcomes (healthcare professionals’ satisfaction with the care they provide, resource use, patients’ acceptance, confidence in, or satisfaction with the intervention, patients’ experiences/perceptions of healthcare professionals acceptance, confidence in or satisfaction with the intervention, healthcare professionals’ acceptance, confidence in or satisfaction with the intervention, adverse events, and equity) were either not reported or were poorly reported. We therefore cannot conclude regarding these effects.

Overall completeness and applicability of evidence

We did not find any studies that had tested the effect of the other types of patient-mediated interventions that we had pre-defined, including patient feedback about clinical practice, patient-led training of healthcare professionals, or having patients as members of committees or boards.

The majority of the studies were carried out in USA (20 of 25 studies), which may limit the applicability of the findings to other settings. Also, most studies aimed at improving professional practice among physicians, usually in a primary care setting and the applicability to other types of health care providers and other care settings is unclear.

Improved professional practice should translate into improvements in patient outcomes. The combination of low-certainty evidence for many professional practice-outcomes and the scarcity of data on patient health outcomes hindered us from drawing any inferences on the association between the two.

Certainty of the evidence

We used the GRADE approach to assess the certainty of the evidence. The certainty of the evidence was judged to be moderate and low for our primary outcome, adherence to recommended clinical practice; very low to low for patient health outcomes; and very low to low for patient satisfaction outcomes. See Summary of findings for the main comparison; Summary of findings 2; Summary of findings 3; and Summary of findings 4 for GRADE judgements.

Potential biases in the review process

Due to wide variation in the terms and definitions used in this field of research, we performed comprehensive literature searches that covered as many of the potentially relevant terms as possible. These searches identified a very large number of primary studies (over 12,000) which we assessed in order to identify the 25 included studies. Given the comprehensive nature of the searches that we used, we are fairly confident that the risk that we have missed important relevant published studies is low. The decision to merge ‘no intervention’ and ‘usual care’ comparisons is based on our interpretation of the comparison group descriptions in the studies. These descriptions varied greatly and made the grouping challenging. However, we are fairly confident that the two comparisons are sufficiently similar to be merged. Two review authors independently screened potentially eligible studies for inclusion and assessed risk of bias in the included studies. None of the review authors had any conflicts of interest.

Agreements and disagreements with other studies or reviews

The effect size for the primary outcome is considered small to moderate, and is in agreement with findings of previous systematic reviews assessing the effects of different interventions to improve professional practice. Audit and feedback probably improves professional practice, but the effectiveness ranges from little or no effect to a substantial effect (Ivers 2012). Reminders, such as computer-generated reminders delivered on paper to healthcare professionals, probably improve professional practice (Arditi 2017). Printed educational material may also improve professional practice, but the effect seems small, and the certainty of the evidence is
low (Giguère 2012). Educational meetings or educational outreach visits may result in modest improvements in professional practice (Forsetlund 2009; O’Brien 2007). Using local opinion leaders may improve professional practice (Flodgren 2011a), as may financial incentives (Flodgren 2011b). Another recent Cochrane review shows that clinical practice guidelines accompanied by tools intended to improve the use of the guideline probably improve adherence to clinical practice (Flodgren 2016). Organisational interventions, such as provision of pharmaceutical care, medication reviews, follow-up visits by a healthcare professional including a pharmacist, nurse or physician, probably make little or no difference in medication errors by primary healthcare professionals in adult patients that lead to hospital admissions, emergency department visits, and death (Khalil 2017).

**Authors’ Conclusions**

**Implications for practice**

Our findings show that some patient-mediated interventions are relevant approaches to improving professional practice.

We are moderately certain about the positive effects that patient-reported health information and patient education can have on professional practice. Thus, it seems reasonable to conclude that these types of patient mediated interventions can contribute to improving the quality of health care services.

However, we cannot be certain that all types of patient-mediated interventions are relevant due to lack of relevant research for several types of interventions such as patient feedback about clinical practice, patients being members of committees or boards, or patient-led training or education of healthcare professionals. We also know too little about the effects on patients’ acceptance, confidence in, or satisfaction with the intervention; patients’ experiences/perceptions of healthcare professionals’ acceptance, confidence in or satisfaction with the intervention; healthcare professionals’ satisfaction with the care they provide; healthcare professionals’ acceptance, confidence in or satisfaction with the intervention; adverse events; and equity.

**Implications for research**

Patient-mediated interventions can be defined in various ways, and a common taxonomy or understanding of the term is lacking (Ng 2017). Consequently, categorising various types of patient-mediated interventions can be challenging - as we experienced when we prepared this review. For instance, to draw a clear line between patient information and patient education interventions has not been straightforward and is, to a large extent, limited to our interpretation of their definitions. The field would likely benefit from having a common framework for defining and classifying patient-mediated interventions. As with many other behavioural change interventions, the interventions in this field are sometimes based on explicit theoretical approaches, but often they are not (Gagliardi 2016; Ng 2017). The importance of basing interventions on theory is contested (Oxman 2005), but a clearer understanding of the mechanisms through which patient-mediated interventions may work would likely be helpful.

In addition to the challenge of categorising different types of patient-mediated interventions, we also had difficulties with the categorisation of comparisons. Terms like “usual care”, “standard care”, “common practice”, “enhanced usual care”, “no intervention” etc. are often used, but these are not necessarily self-explanatory: Usual care can vary tremendously across time and study setting. This, and the fact that many studies do not describe what “usual care” entailed, makes it hard to assess how similar the comparison groups were in the different studies. In future studies more emphasis should be put in carefully describing both the intervention under study and the conditions that applied to the comparison group.

There are several systematic reviews on, for instance, patient education that have reported on relevant patient health outcomes (Anderson 2017; Attridge 2014; Bennett 2016; Clarkesmith 2017; Fryer 2016; Kelly 2018; Kroon 2014; Lenferink 2017; McBain 2016; McCallum 2017; Parreira 2017; Peytreman-Bridevaux 2015; Poquet 2016; Zwerink 2014). These do not, however, provide answers about impacts on professional practice. It would be of great interest to assess if a patient education intervention that meets this review’s definition of a ‘patient-mediated’ intervention would have the same effect on patient health as a patient education intervention not defined as “patient-mediated intervention”. Where interventions have an added focus on healthcare professionals’ performance, does this lead to important gains in patient health? The effects on patient health reported in the studies included in this review can thus more likely provide answers regarding the linkage, if any, between health outcomes and clinical performance more than studies that do not measure clinical performance simultaneously.

From our findings, little can be said about the resource use and cost-effectiveness of these types of interventions, as these outcomes were not usually assessed. Also, we know little about the relative effect of patient-mediated interventions compared to other approaches directed at healthcare professionals, such as audit and feedback, reminders, education etc., as we did not identify any studies that compared these interventions.

We did not find any studies reporting on patients’ trust in healthcare professionals. We therefore need more studies that compare patients’ trust levels after different patient-mediated interventions to enable us to draw conclusions about these effects. In future studies it would be of great interest to compare how patient-mediated interventions affect the communicative common ground between a patient and a healthcare professional.
ACKNOWLEDGEMENTS

We thank Mette Haaland-Overy from Norwegian National Advisory Unit on Learning and Mastery in Health for her consumer input on the protocol. A great thank you to the Norwegian Cancer Society for pointing out the importance of conducting this review and for guidance and co-operation throughout the process. We would like to thank Elizabeth J Paulsen from the Cochrane Effective Practice and Organisation of Care (EPOC) Group, for her support and expertise in editing and submitting the review. We are also very grateful to the EPOC Editor Simon Lewin and peer-reviewers for providing insightful comments and suggestions to improve the review.

The Norwegian Satellite of the EPOC Group receives funding from the Norwegian Agency for Development Cooperation (Norad), via the Norwegian Institute of Public Health to support review authors in the production of their reviews.

## CHARACTERISTICS OF STUDIES

### Characteristics of included studies  
**[ordered by study ID]**

### Alder 2005

| Methods | **Study design:** randomised trial.  
**Number of study arms:** 4.  
**Unit of randomisation:** patient (parent).  
**Study period:** Aug - Dec 2000.  
**Measurement points of outcomes:** post intervention.  
**Analysis method:** not reported. |
|---|---|

| Participants | **Setting**  
**Healthcare setting:** primary care (2 primary care clinics).  
**Country:** USA.  
**Patients**  
**Inclusion/exclusion criteria:** parents of children aged 1 to 10, with complaints of ear pain, sore throat, cough, congestion and/or fever that had not received antibiotic therapy during the previous two weeks  
**Numbers of patients:** 40 (in study n = 80 with 4 arms).  
In intervention: 20.  
In comparison: 20.  
(In arm 3 n = 20 and in arm 4 n = 20).  
**Characteristics of patients (children):**  
- Age: intervention; 3.2 years (SD = 3.0), comparison; 3.7 years (SD = 2.7).  
- Gender: females total 66/80 (82.5%). Intervention; 20/20 (100%), comparison; 16/20 (80%).  
- Health conditions: children with complaints of ear pain, sore throat, cough, congestion and/or fever.  
**Healthcare professionals**  
**Type of healthcare professionals:** physicians.  
**Inclusion/exclusion criteria:** not reported.  
**Numbers of healthcare professionals:** totals not reported.  
In intervention: not reported.  
In comparison: not reported.  
**Characteristics of healthcare professionals:**  
- Age: not reported.  
- Gender: not reported.  
- Experience/specialisation: not reported. |

| Interventions | **Description of patient-mediated intervention:** a combination of a communication promotion intervention and antibiotic information intervention. Antibiotic information was provided first, then, once the parent had been encouraged to use antibiotics for his or her child only when necessary, the researcher transitioned to the communication intervention  
**Patient-mediated intervention category:** patient education.  
**Comparison:** usual care (placebo-like). Child nutrition was the focus of the comparison (The study had a third and fourth arm not addressed here consisting of the patient-mediated intervention without the communication component and patient-mediated |
intervention without the antibiotic information component, respectively)

### Outcomes

**Relevant primary outcomes**

**Antibiotic prescriptions**

*Measurement:* not reported, but most likely patient-reported (parent).

*Unit of measurement:* odds ratio (OR), absolute numbers not reported.

**Relevant secondary outcomes**

**General satisfaction**

**Interpersonal manner**

**Time spent with doctor**

*Measurement:* patient-reported (parents).

*Unit of measurement:* P values for group differences, absolute numbers not reported

*Primary outcome in study:* not reported.

### Notes

We attempted to contact the first author. No reply received. Findings are descriptively reported, and not included in meta-analysis

**Funding:** not reported.

**Conflict of interest:** not reported.

### Methods

**Study design:** randomised trial.
**Number of study arms:** 2.
**Unit of randomisation:** healthcare professional (1 patient per healthcare professional)
**Study period:** Jul 2006 - May 2007.
**Measurement points of outcomes:** 3 months post intervention.
**Analysis method:** ITT (reported by study authors).

### Participants

**Setting**
Healthcare setting: primary care clinic (of a large teaching hospital).
Country: USA.

**Participants**
Inclusion/exclusion criteria: Latino immigrant Spanish-speaking patients, 50 years or older, who used the primary care facility as their regular source of care for at least the previous two years. Exclusion: those with current CRC screening, with gastrointestinal symptoms, a personal history of cancer, a family history of CRC, who had a visit with a physician with a patient already in the study, and those who did not consent to participate.

**Numbers of participants:** 65.
In intervention: 31.
In comparison: 34.

**Characteristics of participants:**
- Age: intervention; 57.6 years (SD = 6.4), comparison; 58.9 years (SD = 7.05).
- Gender: females total 33/65 (51%). Intervention; 16/31 (52%), comparison;16/34 (47%).
- Health conditions: Latino immigrant population, Spanish-speaking, 50 years or older.

**Healthcare professionals**
Type of healthcare professionals: physicians.
Inclusion/exclusion criteria: not reported.

**Numbers of healthcare professionals:** 65.
In intervention: 31.
In comparison: 34.

**Characteristics of healthcare professionals:**
- Age: not reported.
- Gender: females total 32/65 (50.5%).
- Experience/specialisation: not reported.

### Interventions

**Description of patient-mediated intervention:** patients were shown a Spanish language colorectal cancer educational video on a portable personal digital video device while they waited for their visits. They were also given a brochure summarising the video and a one-page reminder to hand to their physician.

**Patient-mediated intervention category:** patient information.

**Comparison:** usual care. No more information provided.

### Outcomes

**Relevant primary outcomes**
**Physician recommendation of screening**
**Measurement:** medical record.
**Unit of measurement:** absolute numbers.

**Relevant secondary outcomes**
No relevant outcomes reported.
Aragones 2010  (Continued)

* Primary outcome in study: CRC screening completion. Secondary outcomes were physician recommendation of any CRC screening test recommended in the guidelines and patient adherence to physician CRC screening recommendation

| Notes | Funding: Centers for Disease Control and Prevention (CDC). Conflict of interest: none disclosed. |

### Methods

**Study design:** cluster-randomised trial.  
**Number of study arms:** 3 (4 arms, but two control arms were lumped together and analysed as one group)  
**Unit of randomisation:** practice.  
**Study period:** Mar - Jul 1988.  
**Measurement points of outcomes:** post intervention (immediately after the medical visit).  
**Analysis method:** not reported.

### Participants

**Setting**  
*Healthcare setting:* primary care (4 medical clinics).  
*Country:* USA.

**Patients**  
*Inclusion/exclusion criteria:* patients who scored above 3 or more in 12-item version of the General Health Questionnaire (GHQ)  
*Numbers of patients:* 79 (in study n = 103 with 3 arms).  
In intervention: 29.  
In comparison: 50 (from two control arms).  
(In arm 3 n = 24).  

**Characteristics of patients:**  
- **Age:** intervention; 60.1 years (SE = 2.7), comparison; 53.4 years (SE = 2.3).  
- **Gender:** females total 60/79 (75.9%). Intervention; 24/29 (83%), comparison; 36/50 (71%).  
- **Health conditions:** general patient population with an increased risk of mental health problems.

**Healthcare professionals**  
*Type of healthcare professionals:* physicians.  
*Inclusion/exclusion criteria:* not reported.  
*Numbers of healthcare professionals:* not reported.  
In intervention: not reported.  
In comparison: not reported.  

**Characteristics of healthcare professionals:**  
- **Age:** not reported.  
- **Gender:** patients seen by female physicians: intervention; 4/29 (14%), comparison; 25/50 (50%).  
- **Experience/specialisation:** physician’s years of training: intervention; 2.3 (SE = 0.3) years, comparison: 1.8 (SE = 0.1) years.

### Interventions

**Description of patient-mediated intervention:** physicians received information about their patient's mental health problem prior to seeing that patient  
**Patient-mediated intervention category:** patient-reported health information about own health/needs/concerns  
**Comparison:** no intervention. Two of the four clinics served as controls, since the residents in these clinics were not exposed to either of these two interventions. These two clinics differed from each other, however, in the level of the residents’ awareness of this study. Residents in one of these clinics were asked to complete a questionnaire after seeing each study patient. The residents in the other clinic were not asked to complete these questionnaires and were, therefore, less likely to be cognizant of this study. (The study had a third arm not addressed here consisting of the patient-mediated inter-
Relevant primary outcomes
*Counselling items by healthcare professional*
Measurement: two separate reports: patient-reported and healthcare professionals reported
Unit of measurement: average numbers of counselling items (means +/- SD).

Relevant secondary outcomes
*Patients with a psychological disorder*
*Control over stress*
* Primary outcome in study: not reported.

**Notes**
Conflict of interest: not reported.

Other bias  
| Low risk |
|---|---|

This is a cluster-randomised trial and thus we have judged additional sources of potential bias:
- Recruitment bias: 91% agreed to participate.
- Baseline imbalance: no demographic baseline imbalance.
- Loss of clusters: none of the clusters were lost.
- Incorrect analysis: we did not attempt to re-analyse studies that were not pooled in a meta-analysis.
- Comparability with individually randomised trials: no indication that this study had risk of herd-effect bias.

**Caskey 2011**

Methods  
| Study design: cluster-randomised trial.  
| Number of study arms: 2.  
| Unit of randomisation: healthcare professional.

| Other bias | Unclear risk | This is a cluster-randomised trial and thus we have judged additional sources of potential bias  
  • Recruitment bias: insufficient |
information to permit judgement of ‘Low risk’ or ‘High risk’.
  • Baseline imbalance: insufficient information to permit judgement of ‘Low risk’ or ‘High risk’.
  • Loss of clusters: loss of clusters is not addressed in the available abstract.
  • Incorrect analysis: for the five studies in which healthcare professionals were the unit of randomisation the median ICC among similar studies for our primary outcome was 0.000 (95% CI; 0, 0.142) according to the University of Edinburgh’s Database of ICCs (ABDN 2015). The effective sample sizes of these studies were thus the same as reported by the study authors.
  • Comparability with individually randomised trials: no indication that this study had risk of herd-effect bias.

Christy 2013

| Methods | Study design: randomised trial.  
Number of study arms: 2.  
Unit of randomisation: patient.  
Study period: 2008 - 2010.  
Measurement points of outcomes: post intervention (1 week after).  
Analysis method: per protocol (reported by study authors). |
|---------|-------------------------------------------------|

| Participants | Setting  
Healthcare setting: primary care clinics (11 clinics).  
Country: USA.  
Patients  
Inclusion/exclusion criteria:  
Inclusion: self-identified as black or African-American, 51-80 years, English-speaking, and currently non-adherent to CRC screening guidelines.  
Exclusion: personal history of CRC or adenomatous polyps requiring surveillance colonoscopy; medical condition precluding CRC screening; cognitive, speech, or hearing impairment; and current adherence to CRC screening guidelines  
Numbers of patients: 817.  
In intervention: 407.  
In comparison: 410.  
Characteristics of patients:  
• Age: intervention: 56.8 years (SD = 6.0), comparison: 57.8 years (SD = 6.4).  
• Gender: females total 345/659 (52.3%). Intervention: 165/319 (52%), comparison: 180/340 (53%).  
• Health conditions: general primary healthcare population. |
### Healthcare professionals

Type of healthcare professionals: primary care provider (physician).

Inclusion/exclusion criteria: not reported.

Numbers of healthcare professionals: 164.

In intervention: not reported.

In comparison: not reported.

Characteristics of healthcare professionals:
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

### Interventions

**Description of patient-mediated intervention:** a clinic-based, computer-delivered tailored interactive program about colorectal cancer screening

**Patient-mediated intervention category:** patient information.

**Comparison:** usual care (patient information-like). Non-tailored brochure about colorectal cancer screening provided at the clinic.

### Outcomes

**Relevant primary outcomes**

Primary care provider write an order for a colorectal cancer screening test

**Measurement:** medical records.

**Unit of measurement:** relative numbers, odds ratio.

**Doctor recommended fecal occult blood test (FOBT)**

**Doctor recommended colonoscopy**

**Measurement:** patient-reported.

**Unit of measurement:** relative numbers, odds ratio. They were reported as predictors for another outcome “self-reported screening discussion with primary care provider”

**Relevant secondary outcomes**

No relevant outcomes reported.

* Primary outcome in study: colorectal cancer screening test discussion

### Notes

**Funding:** funded by the National Cancer Institute at the National Institutes of Health

**Conflict of interest:** none disclosed.

### Goldberg 2012

**Methods**
- **Study design:** randomised trial.
- **Number of study arms:** 2.
- **Unit of randomisation:** healthcare professional.
- **Study period:** April 2011 - May 2012.
- **Measurement points of outcomes:** post intervention (immediately after the medical visit post intervention)
- **Analysis method:** ITT (reported by study authors).

**Participants**
- **Setting:**
  - **Healthcare setting:** hospital (children's hospital).
  - **Country:** USA.
- **Patients**
  - **Inclusion/ exclusion criteria:**
    1. child aged 1-17 years presenting with a chief complaint consistent with an asthma exacerbation, such as wheeze or trouble breathing,
    2. the child had a history of asthma by parent report, and
    3. the visit was believed to be consistent with an asthma exacerbation by the treating attending.
  - **Exclusion:** patients were excluded if the treating physician was not part of the study, the child had a major pulmonary or cardiac comorbid illness, the child’s parent was non-English speaking, or if the child was triaged to the med-trauma bay for severe respiratory distress
  - **Numbers of patients:** 77 children.
  - In intervention: 40.
  - In comparison: 37.
- **Characteristics of patients:**
  - Age: mean of 8 years old. Intervention; 7.4 years (SD = 5.0), comparison; 8.8 years (SD = 4.4).
  - Gender: females total 52%. Intervention; 53%, comparison; 51%.
  - Health conditions: asthma.
- **Healthcare professionals**
  - **Type of healthcare professionals:** physicians.
  - **Inclusion/exclusion criteria:** not reported.
**Goldberg 2012 (Continued)**

<table>
<thead>
<tr>
<th>Numbers of healthcare professionals:</th>
<th>17. In intervention: not reported. In comparison: not reported.</th>
</tr>

<tbody>
<tr>
<td>Characteristics of healthcare professionals:</td>
<td>• Age: not reported. • Gender: not reported. • Experience/specialisation: all physicians involved in the study were board-certified in paediatrics and paediatric emergency medicine.</td>
</tr>
</tbody>
</table>

### Interventions

**Description of patient-mediated intervention:** parents of children with asthma filled out a questionnaire (PACCI-ED) that measures five domains of asthma health: 1) current control, 2) trajectory, 3) risk, 4) medication adherence and 5) burden. The physicians allocated to this intervention group received the PACCI-ED filled out by parents and were told what it is used for and that they could use it to complete the clinician assessment form.

**Patient-mediated intervention category:** patient-reported health information about own health/needs/concerns

**Comparison:** no intervention. Physicians in this group had no known exposure to the PACCI-ED before or during the study. They completed the questions on the clinician assessment form also.

### Outcomes

**Relevant primary outcomes**
- Correctly identified level of chronic asthma control
- Correctly identified child’s asthma trajectory
- Correctly identified level of medication adherence
- Correctly identified degree of disease burden to the family

**Measurement:** clinician assessment form.

**Unit of measurement:** per cent.

**Relevant secondary outcomes**
- Not relevant outcomes reported.

* Primary outcome in study: all four outcomes.

### Notes

**Funding:** Rhode Island Hospital (described in protocol).

**Conflict of interest:** none disclosed.

Herman 1995

**Methods**

**Study design:** cluster-randomised trial.
**Number of study arms:** 3.
**Unit of randomisation:** practice (3 practices in total).
**Study period:** Oct 1989 - Mar 1990.
**Measurement points of outcomes:** 3 months post intervention.
**Analysis method:** not reported.

**Participants**

**Setting**
**Healthcare setting:** public hospital (3 practices).
**Country:** USA.

**Patients**
**Inclusion/exclusion criteria:** all women older than 65 years attending the ambulatory medical clinic were included

**Numbers of patients:**
Total: 839 randomised to 3 arms (not reported the totals for the two arms relevant here)
In intervention: not reported (provided only for subgroups of women)
In comparison: not reported (provided only for subgroups of women)
(In arm 3: n = not reported (provided only for subgroups of women))

**Characteristics of patients:**
- Age: among women without prior clinical breast examination (n = 540):
  intervention: 73.8 years (SD =6.7), comparison: 73.5 years (SD = 8.5). Among women without prior mammography (n = 471):
  intervention: 71.4 years (SD = 6.7), comparison: 72.5 years (SD = 6.3).
- Gender: all females.
- Health conditions: general patient population of females 65 years or older.
### Healthcare professionals

**Type of healthcare professionals:** physicians.

**Inclusion/exclusion criteria:** not reported.

**Numbers of healthcare professionals:** 45 (n = 66 for all 3 arms).

- In intervention: 22.
- In comparison: 23.
  (In arm 3 n = 21)

**Characteristics of healthcare professionals:**
- **Age:** not reported.
- **Gender:** reported as "no significant cross-group differences in gender".
- **Experience/specialisation:** reported as "no significant cross-group differences in physician's level of training".

### Interventions

**Description of intervention patient-mediated:** in the clinic assigned to intervention, educational materials were given to the patient by the nurse at each clinic visit. The nurses used the "What Every Woman Should Know About Mammography" pamphlet, as well as an additional sheet outlining the specific importance of mammography for the older woman.

**Patient-mediated intervention category:** patient information.

**Comparison:** no intervention (placebo-like). A monograph with breast screening recommendations and a lecture on preventive services was also provided bimonthly as part of an ambulatory services lecture series.

(The study had a third arm not addressed here consisting of the patient-mediated intervention plus a prevention team)

### Outcomes

**Relevant primary outcomes**

- **Number of women offered mammogram**
- **Number of women offered clinical breast exam**

**Measurement:** medical records.

**Unit of measurement:** per cent of women.

- **Number of women offered clinical breast examination among those not previously having a clinical breast exam**
- **Number of women offered mammography among those not previously having a mammography**

**Measurement:** medical records.

**Unit of measurement:** absolute numbers of women without previous clinical breast examination or mammography.

**Relevant secondary outcomes**

- No relevant reported.
- * Primary outcome in study: not reported.

### Notes

**Funding:** the Case Western Reserve University Teaching Nursing Home Program.

**Conflict of interest:** not reported.

</tbody>
</table>
| | | • Incorrect analysis: the effective total sample size for the three cluster-randomised studies included in our meta-analyses were calculated and are listed in Table 2.
**Jacobson 1999**

| Methods | Study design: randomised trial.  
Number of study arms: 2.  
Unit of randomisation: patient.  
Study period: May - June 1998.  
Measurement points of outcomes: post intervention (immediately after the medical visit).  
Analysis method: ITT (reported by study authors). |
|---------|-------------------------------------------------|
| Participants | Setting  
Healthcare setting: hospital (ambulatory care clinic in a public teaching hospital)  
Country: USA.  
Patients  
Inclusion/exclusion criteria:  
Inclusion: visits to follow management of hypertension, diabetes, heart failure, or other chronic medical problems.  
Exclusion: Patients not meeting these inclusion criteria, in addition to those with chart-documented receipt of the vaccine within the past 5 years, walk-in visits, first visits, medication-refill visits in which patients did not see their primary care providers, blind patients, patients with clinically documented dementia, and non English-speaking patients were excluded  
Numbers of patients: 433.  
In intervention: 221.  
In comparison: 212.  
Characteristics of patients:  
- Age: total 63.08 years (SD = 12.73). Intervention; 64.2 years (SD = 13.13), comparison: 61.92 years (SD = 12.23).  
- Gender: total females 300/433 (69.3%). Intervention; 161/221 (72.9%), comparison; 139/212 (65.6%).  
- Health conditions: general patient population with at least one indicator for vaccine such as age, cardiac disease, pulmonary disease, or alcohol abuse.  
Healthcare professionals  
Type of healthcare professionals: physicians (house officers) (n = 148), physician assistants (n = 2) and nurse practitioners (n = 6)  
Inclusion/exclusion criteria: not reported.  
Numbers of healthcare professionals: 156.  
In intervention: not reported.  
In comparison: not reported.  
Characteristics of healthcare professionals:  
- Age: Not reported.  
- Gender: Not reported.  
- Experience/specialisation: the clinicians were supervised by the University faculty who review all patient care. All clinicians may initiate orders for pneumococcal vaccine, |
and attending physicians cosign these orders.

### Interventions

**Description of patient-mediated intervention:** one-page, low-literacy (below fifth-grade level) educational handout encouraging patients to "ask your doctor about the pneumonia shot"

**Patient-mediated intervention category:** patient information.

**Comparison:** usual care (placebo-like). 1-page, low-literacy educational handout to patients conveying information about nutrition

### Outcomes

**Relevant primary outcomes**

- **Clinician recommended vaccine**
  - **Measurement:** patient-reported.
  - **Unit of measurement:** absolute numbers.

- **Administration of the vaccine at that clinic visit**
  - **Measurement:** medical record.
  - **Unit of measurement:** absolute numbers.

**Relevant secondary outcomes**

No relevant outcomes reported.

* Primary outcome in study: administration of the vaccine at that clinic visit and discussion about the vaccine

### Notes

**Funding:** the National Vaccine Program, Centers for Disease Control and Prevention and the Georgia Emerging Infections Program, Atlanta, Ga. Also funded by Indigent Care Trust Funds from the State of Georgia to the Office of Health Promotion and Disease Prevention at Grady Health Systems

**Conflict of interest:** not reported.

### Kattan 2006

#### Methods
- **Study design:** randomised trial.
- **Number of study arms:** 2 (2 x 2 factorial design).
- **Unit of randomisation:** patient.
- **Study period:** Oct 1998 - Aug 2000.
- **Measurement points of outcomes:** post intervention (months 4-14 while the intervention was running. Outcome time point reported as “during the intervention year”)
- **Analysis method:** ITT (reported by study authors).

#### Participants
- **Setting**
  - Healthcare setting: inpatient units of hospitals, emergency departments (EDs), and community paediatric clinics
  - Country: USA.
- **Patients**
  - **Inclusion/exclusion criteria:** eligibility was limited to residents of census tracts in which 20% or more of households had incomes below the federal poverty level except in Seattle, where patients could be enrolled if they met Medicaid eligibility. Other inclusion criteria included a history of 1 or more hospitalisation or 2 unscheduled visits for asthma in the previous 6 months and a positive allergy skin test to 1 or more of 11 indoor allergens. Children were excluded if they made 2 or more visits to an asthma specialist or asthma clinic in the previous 6 months or if they had any other serious chronic illness
  - **Numbers of patients:** 937 children.
  - In intervention: 471.
  - In comparison: 466.
- **Characteristics of patients:**
  - Age: total mean age 7.7 years (5 to 11 years). Intervention; 7.7 years, comparison; 7.6 years. No SD reported.
  - Gender: female total 360/937 (38.4%). Intervention; 186/471 (39.5%), comparison; 173/466 (37.1%).
  - Health conditions: moderate to severe asthma.
- **Healthcare professionals**
  - **Type of healthcare professionals:** physicians, nurse practitioners, physician's assistants.
  - **Inclusion/exclusion criteria:**
  - **Numbers of healthcare professionals:** total number not reported.
  - In intervention: 435 healthcare professionals.
In comparison: not reported.

**Characteristics of healthcare professionals:**
- Age: not reported
- Gender: not reported
- Experience/specialisation: 82.8% were attending physicians (355/435) and years in practice were in average 12.6 (SD = 9).

### Interventions

**Description of patient-mediated intervention:** computer-generated letters based on information collected from the child’s carer through bi-monthly telephone calls (CATI calls) conducted by the centralised service for all the study sites. The letter to the physician caring for that child summarised the child’s asthma symptoms, health service use, and medication use with a corresponding recommendation to step up or step down medications (in accordance with guidelines)

**Patient-mediated intervention category:** patient-reported health information about own health/needs/concerns

**Comparison:** no intervention. computer-generated letters were not sent to the healthcare professionals of children in the comparison group. For this group, the information from the CATI calls was used to determine what recommendation would have been generated had the child been in the intervention group

### Outcomes

**Relevant primary outcomes**

*Change in medication when indicated (by guidelines)*

**Measurement:** patient-reported. Changes in medications were determined from the CATI call after a scheduled visit. Step up in medications was defined as an increase from no antiinflammatory use to any anti-inflammatory use or from occasional to daily anti-inflammatory use

**Unit of measurement:** the number of patients with changed medication from the amount of step-up letters sent to physicians

**Relevant secondary outcomes**

*Symptoms because of asthma per 2 weeks*
- Maximum symptom days.
- Days limited in activities for more than half day.
- School days missed.

**Measurement:** patient-reported. Determined from the CATI call after a scheduled visit

**Unit of measurement:** continuous. How many times or on a scale.

* Primary outcome in study: not reported.

### Notes

We attempted to contact the first author. No reply received.

### Methods

**Study design:** cluster-randomised trial.
**Number of study arms:** 4.
**Unit of randomisation:** healthcare professional.
**Study period:** 2 months.
**Measurement points of outcomes:** post intervention (outcomes were measured during the two months the study was running)
**Analysis method:** ITT (reported by study authors).

### Participants

**Setting**
*Healthcare setting:* primary care (family practices).
*Country:* New Zealand.

**Patients**
*Inclusion/exclusion criteria:* 50 years or older, no known diabetes, no glucose test within the last three years visiting a healthcare professional
*Numbers of patients:* 3189 (n = 5628 with 4 arms).
In intervention: 1639.
In comparison: 1550.
(In arm 3 n = 983 and in arm 4 n = 1456).

*Characteristics of patients:*
- **Age:** intervention; 63.9 years (SD = 10.95), comparison; 64.2 years (SD = 11.3)
- **Gender:** females total 861/3189 (27%). Intervention; 551/1639 (33.6%), comparison; 310/1550 (20%).
- **Health conditions:** general primary care population that were 50 years or older.

**Healthcare professionals**
*Type of healthcare professionals:* family practitioners.
*Inclusion/exclusion criteria:* family practitioners were eligible for the study if they: 1) used a specific patient management computer software, 2) recorded their medical consultation notes on the computer within their consultations, 3) had received laboratory glucose results electronically for at least 1 year, 4) saw at least 10 individual patients aged 50 years or older per month, and 5) worked in the Auckland region
*Numbers of healthcare professionals:* 55 (n = 107 for all 4 arms) and 33 family practices (n = 66 for all 4 arms) randomised
In intervention: 27 family practitioners and 16 practices.
In comparison: 28 family practitioners and 17 practices.
(In arm 3: n = 24 family practitioners and 16 practices. In arm 4: n = 28 family practitioners and 17 practices)

*Characteristics of healthcare professionals:*
- **Age:** not reported.
- **Gender:** females total 49/107 (46%). Intervention; 13/27, comparison; 13/28.
- **Experience/specialisation:** median years since family practitioner graduated was 18 (range 30) in intervention and 19 (range 28) in comparison.

### Interventions

**Description of patient-mediated intervention:** for healthcare professionals allocated to this intervention their patients filled out a diabetes risk self-assessment form and gave the filled out form to the healthcare professional (family practitioner) before the consultation. The form, which was adapted from the American Diabetes Association contained information asked patients about their age, ethnicity, weight (body mass index) , whether they had a near family members with diabetes, whether they were a woman who had a baby weighing more than 4 kg at birth, and exercise habits
Patient-mediated intervention category: patient-reported health information about own health/needs/concerns
Comparison: no intervention (placebo-like). All healthcare professionals, before group assignment, were visited by research staff to inform about the study, and to provide uniform education on diabetes screening and on how to use both the computer reminder and the patient form (PROMs). A copy of a recent article on diabetes screening and a laminated card summarising the same information was also given each healthcare professional
(The study had a third and fourth arm not addressed here consisting of reminder to healthcare professional and patient-mediated intervention plus a reminder to healthcare professional, respectively)

| Other bias                                         | Low risk    | This is a cluster-randomised trial and thus we have judged additional sources of potential bias:  
- Recruitment bias: no indication that recruitment was biased.  
- Baseline imbalance: no baseline imbalance.  
- Loss of clusters: none of the clusters were lost.  
- Incorrect analysis: for the five studies in which healthcare professionals were the unit of randomisation, the median ICC among similar studies for our primary outcome was 0.000 (95% CI; 0, 0.142) according to the University of Edinburgh's Database of ICCs *(ABDN 2015)*. The effective sample sizes of these studies were thus the same as reported by the study authors.  
- Comparability with individually randomised trials: no indication that this study had risk of herd-effect bias. |
## Methods

**Study design:** randomised trial.  
**Number of study arms:** 2.  
**Unit of randomisation:** patient.  
**Study period:** Feb 2007 - Jun 2008.  
**Measurement points of outcomes:** 2 months post intervention.  
**Analysis method:** ITT (reported by study authors).

## Participants

**Setting**  
*Healthcare setting:* clinic (urban diabetes self-management clinic that serves uninsured patients)  
*Country:* USA.

**Patients**  
*Inclusion/exclusion criteria:* Inclusion: 18 years or older, verbal fluency in English, and responsibility for their own diabetes self-management  
*Numbers of patients:* 129.  
In intervention: 67.  
In comparison: 62.  
*Characteristics of patients:*  
- Age: intervention: 52.4 years (SD = 11.4), comparison: 50.5 years (SD = 12.0).  
- Gender: females total 55/129 (42.5%). Intervention; 29/67 (43%), comparison; 26/62 (42%).  
- Health conditions: diabetes type 2.

**Healthcare professionals**  
*Type of healthcare professionals:* physicians.  
*Inclusion/exclusion criteria:* not reported.  
*Numbers of healthcare professionals:* not reported.  
In intervention: not reported.  
In comparison: not reported.  
*Characteristics of healthcare professionals:*  
- Age: not reported.  
- Gender: not reported.  
- Experience/specialisation: trained in internal medicine.

## Interventions

**Description of patient-mediated intervention:** patients were given waiting room-administered, low-literacy, computer multimedia diabetes education program  
**Patient-mediated intervention category:** patient education.  
**Comparison:** usual care (patient information-like). Patients in this group read an educational brochure. In addition, a short diabetes crossword puzzle based on the brochure was distributed.

## Outcomes

**Relevant primary outcomes**  
*Diabetes medication prescribed*  
*Antihypertensive medications prescribed*  
*Measurement:* patient self-report, routinely verified by clinic physicians  
*Unit of measurement:* absolute numbers.

**Relevant secondary outcomes**  
*HbA1c*  
*Measurement:* objective measurements by use of phlebotomy at first visit and 3 months later  
*Unit of measurement:* absolute numbers.
Khan 2011  *(Continued)*

* Primary outcome in study: not reported.

Notes

**Funding:** the American Cancer Society and the National Institute of Mental Health

**Conflict of interest:** none disclosed.
**Methods**

**Study design:** cluster-randomised trial.
**Number of study arms:** 2.
**Unit of randomisation:** healthcare professional.
**Study period:** 2001.
**Measurement points of outcomes:** 12 and 20 weeks post intervention.
**Analysis method:** not reported.

**Participants**

**Setting**
*Healthcare setting:* primary care (general practice).
*Country:* the Netherlands.

**Patients**

*Inclusion/exclusion criteria:*
Inclusion: patients who had been using proton pump inhibitors (PPIs) on prescription (from their general practitioner) for at least 12 weeks. Exclusion: younger than 18 years, not able to fill in a questionnaire in the Dutch language, serious disease, oesophagitis grade C or D

*Numbers of patients:* 160 randomised.
In intervention: 88.
In comparison: 72.

*Characteristics of patients:*
- **Age:** total 74/113 were 55 years or older. Intervention: 42/63 were 55 years or older, comparison: 32/50 were 55 years or older.
- **Gender:** females total 67/113. Intervention: 39/63 (62%), comparison: 28/50 (56%).
- **Health conditions:** patients with dyspepsia.

**Healthcare professionals**

*Type of healthcare professionals:* general practitioner.
*Inclusion/exclusion criteria:* not reported.
*Numbers of healthcare professionals:* 20 in total.
In intervention: 11.
In comparison: 9.

*Characteristics of healthcare professionals:*
- **Age:** not reported.
- **Gender:** not reported.
- **Experience/specialisation:** not reported.

**Interventions**

*Description of patient-mediated intervention:* a simple information leaflet was sent to patients by the GPs in the intervention group. The leaflet gave information about updated recommendations made to GPs about the clinical management of dyspepsia and emphasised the importance of reducing inappropriate use of PPIs. Suggestions were made to reduce or stop using PPIs and advice was given on how to reduce the use and when to seek help from the GP for this. Patients made their own decisions about whether to visit the GP or not. GPs received instruction in a brief visit from a researcher and a flowchart based on the content of the updated Dutch guideline

*Patient-mediated intervention category:* patient information.
*Comparison:* usual care. No more information provided.

**Outcomes**

*Relevant primary outcomes*
- **Stopped or reduced PPI dose**
- **Stopped prescribed PPI**
**Patient outcomes**

- **Dyspepsia severity high**
  - **Measurement:** medical record.
  - **Unit of measurement:** absolute numbers.

**Relevant secondary outcomes**

- **Mental health**
  - **Vitality**
    - **Measurement:** patient-reported.
    - **Unit of measurement:** mean.

* Primary outcome in study: stopped or reduced PPI dose.

Krol 2004  (Continued)

- Recruitment bias: Author’s quote: “Twenty GP’s were recruited” and no indication that this was biased.
- Baseline imbalance: patient groups were similar at baseline.
- Loss of clusters: none of the clusters were lost.
- Incorrect analysis: for the five studies in which healthcare professionals were the unit of randomisation, the median ICC among similar studies for our primary outcome was 0.000 (95% CI; 0, 0.142) according to the University of Edinburgh’s Database of ICCs (ABDN 2015). The effective sample sizes of these studies were thus the same as reported by the study authors.
- Comparability with individually randomised trials: no indication that this study had risk of herd-effect bias.

Leveille 2009

Methods
Study design: randomised trial.
Number of study arms: 2.
Unit of randomisation: patient.
Measurement points of outcomes: post intervention (in the medical visit) for primary outcome and 1 week and 3 months after the medical visit (post intervention) for secondary outcomes
Analysis method: ITT (reported by study authors).

Participants
Setting
Healthcare setting: hospitals and primary care (2 hospital-based practices and 2 community-based affiliated practices)
Country: USA.
Patients
Inclusion/exclusion criteria:
Inclusion: patients were eligible to participate if they were aged 20 years or older and screened positive for any of our 3 target conditions: chronic musculoskeletal pain, mobility difficulty, or depression
Exclusion: patients currently receiving care for their chronic condition from a specialist physician or therapist
Numbers of patients: 241.
In intervention: 121.
In comparison: 120.
Characteristics of patients:
- Age: total 52.4 years (SD = 12.25), intervention; 51.9 years (SD = 13.1),
comparison; 52.9 years (SD = 11.3).

- Gender: females total 138/241 (57.3%). Intervention; 71/121 (58.7%),
  comparison; 67/120 (55.8%).

- Health conditions: primary care patients with chronic conditions scheduled with
  primary care practitioner appointments.

### Healthcare professionals

**Type of healthcare professionals:** primary care practitioners.

**Inclusion/exclusion criteria:** not reported.

**Numbers of healthcare professionals:** not reported.

In intervention: not reported.

In comparison: not reported.

**Characteristics of healthcare professionals:**
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

### Interventions

**Description of patient-mediated intervention:** patients received a standardised *PatientSite* message from the nurse e-coach that provided a brief description of the screened condition(s) and general tips on how to communicate more effectively with one’s primary care practitioner.

**Patient-mediated intervention category:** patient information.

**Comparison:** usual care (placebo-like). Patients received a general message through *PatientSite* containing URL links to US Government web sites with general health information (home pages for the US Department of Health and Human Services and the Centers for Disease Control and Prevention) (placebo).

Primary care practitioners immediately were sent *PatientSite* messages notifying them of the conditions for which their patients screened positive, regardless of group assignment.

### Outcomes

**Relevant primary outcomes**

**Screened condition identified in the index visit**

**Measurement:** medical record.

**Unit of measurement:** absolute numbers.

**Relevant secondary outcomes**

**Rate the medical care in visit**

**Measurement:** patient-reported.

**Unit of measurement:** on 0-10 scale (best = 10), mean ± SD.

Doctor definitely showed concern about health/feelings.

Doctor definitely spent enough time.

**Measurement:** patient-reported.

**Unit of measurement:** absolute numbers of patients reporting the outcome occurring/happening.

**Pain subscale SF-36 (moderate-severe)**

**Measurement:** patient-reported.

**Unit of measurement:** absolute number of patients reporting the outcome occurring/happening.

**Average pain rating (0-10, 10 is most)**

**Measurement:** patient-reported.

**Unit of measurement:** on 0-10 scale (worst/most = 10), mean ± SD.

* Primary outcome in study: detection and treatment of the target conditions and symp-
Leveille 2009  *(Continued)*

| Risk of bias |  |
| --- | --- | --- |
| Bias | Authors’ judgement | Support for judgement |
| Random sequence generation (selection bias) | Unclear risk | Insufficient information to permit judgement of ‘Low risk’ or ‘High risk’. Author’s quote: “Patients who screened positive and were eligible for the study were automatically randomized to the control or intervention groups stratified by provider” |
| Allocation concealment (selection bias) | Unclear risk | Insufficient information to permit judgement of ‘Low risk’ or ‘High risk’ |
| Blinding of participants and personnel (performance bias) | Unclear risk | Insufficient information to permit judgement of ‘Low risk’ or ‘High risk’ |
| Blinding of outcome assessment (detection bias) | Unclear risk | Insufficient information about the sequence generation process to permit judgement of ‘Low risk’ or ‘High risk’ |
| Incomplete outcome data (attrition bias) | Low risk | Described in detailed flow chart and equal lost to follow-up in both arms. ITT-analysis |
| Selective reporting (reporting bias) | Low risk | Protocol not accounted for, but found at clinicaltrial.gov (NCT00130416). No serious protocol deviations |
| Other bias | Low risk | No indication of other biases. |

Mazonson 1996

| Methods | Study design: cluster-randomised trial.  
Number of study arms: 2.  
Unit of randomisation: healthcare professional.  
Study period: about 1 year.  
Measurement points of outcomes: post intervention.  
Analysis method: not reported. |  |
Participants

**Setting**
Healthcare setting: primary care (Health Maintenance Organisation (HMO)).
Country: USA.

**Patients**
Inclusion/exclusion criteria:
Inclusion: 21-65 years and symptoms of anxiety and/or depression on Hopkins Symptom Checklist (SCL-90) above 'threshold' on two occasions
Exclusion: previously diagnosed mental health condition or received treatment in the past 6 months

*Numbers of patients:* 618.
In intervention (patient-mediated intervention): 389.
In comparison: 229.

*Characteristics of patients:*
- **Age:** Intervention; 42 years (SD = 10), comparison group; 44 years (SD = 11).
- **Gender:** Females total 336/573. Intervention; 218/357 (61%), comparison; 118/216 (55%).
- **Health conditions:** General primary care population that were at risk of having or developing anxiety or depression symptoms.

**Healthcare professionals**
Type of healthcare professionals: Primary care physicians.
Inclusion/exclusion criteria: Not reported.

*Numbers of healthcare professionals:* 75 healthcare professionals, representing 23 practices.
In intervention (patient-mediated intervention): 40.
In comparison: 35.

*Characteristics of healthcare professionals:*
- **Age:** not reported.
- **Gender:** not reported.
- **Experience/specialisation:** mean year of residency completed was 1982 in intervention group and 1978 in comparison group. In the intervention group 66% of the speciality was family practice and 34% was internal medicine. In the comparison group these numbers were 74% and 26%, respectively. In the intervention group 97% had a board certification and in the comparison group the number was 91%. Mean years in practice was 11.2 (SD = 10.3) in intervention group and 13.5 (SD = 9.7) in comparison group. Years in current practice was 10 (SD = 11.2) in intervention group and 11.9 (SD = 10.1) in comparison group. The number of patients seen per day was 24.2 (SD = 4.6) in intervention group and 25.1 (SD = 7.1) in comparison group.

Interventions

**Description of patient-mediated intervention:** the intervention was designed to provide patient self-reported information on anxiety and depression symptoms and disorders to primary care physicians. Patients filled out the forms and a mental health patient profile was created that summarised and given to the treating physician. Along with the patient profile created, the physicians were offered additional support and information from the study researchers in a 1 hour face-to-face meeting. Follow-up information in the patient profiles was provided to the physician at 11 weeks and 5 months. The patients were not aware of their scores

**Patient-mediated intervention category:** patient-reported health information about own health/needs/concerns

**Comparison:** no intervention. No feedback of PROMs scores to physicians or patients.
Mazonson 1996  *(Continued)*

The patient profiles were provided to the comparison physicians after the study.

<table>
<thead>
<tr>
<th>Outcomes</th>
<th>Relevant primary outcomes</th>
</tr>
</thead>
</table>

- Recognition of mental health problems *(any chart notation or description related to anxiety, stress, depression, or other mental health condition)*
- *Unit of measurement:* absolute numbers.

**Relevant secondary outcomes**

No relevant outcomes reported.

- *Primary outcome in study:* chart notation of anxiety, depression, or other mental health diagnoses or symptoms, referral to mental health specialists, prescription of psychotropic medications, hospitalisation, and office visits.

| Notes | Funding: the Upjohn Company.  
Conflict of interest: one author was a former employee at the company that funded the study |

**Risk of bias**

<table>
<thead>
<tr>
<th>Bias</th>
<th>Authors’ judgement</th>
<th>Support for judgement</th>
</tr>
</thead>
</table>

- **Random sequence generation (selection bias)**
  - Unclear risk
  - Insufficient information to permit judgement of 'Low risk' or 'High risk'.

- **Allocation concealment (selection bias)**
  - Unclear risk
  - Insufficient information to permit judgement of 'Low risk' or 'High risk'.

- **Blinding of participants and personnel (performance bias)**
  - High risk
  - No indication of attempting to blind the participants or personnel.

- **Blinding of outcome assessment (detection bias)**
  - Unclear risk
  - Insufficient information to permit judgement of 'Low risk' or 'High risk'.

- **Incomplete outcome data (attrition bias)**
  - Low risk
  - Most physicians in both groups stayed on and all the patient was accounted for.

- **Selective reporting (reporting bias)**
  - Unclear risk
  - Insufficient information to permit judgement of 'Low risk' or 'High risk'. Protocol not accounted for or found in clinicaltrials.gov.

- **Other bias**
  - Low risk
  - This is a cluster-randomised trial and thus we have judged additional sources of potential bias:
    - Recruitment bias: no differences between those asked to participate and the 59% who agreed to participate.
Baseline imbalance: no baseline difference in participating physicians. However, there were several baseline differences among patients.

• Loss of clusters: none of the clusters were lost.

• Incorrect analysis: for the five studies in which healthcare professionals were the unit of randomisation, the median ICC among similar studies for our primary outcome was 0.000 (95% CI: 0, 0.142) according to the University of Edinburgh’s Database of ICCs (ABDN 2015). The effective sample sizes of these studies were thus the same as reported by the study authors.

• Comparability with individually-randomised trials: no indication that this study had risk of herd-effect bias.

McAlister 2005

Methods

Study design: cluster-randomised trial.
Number of study arms: 2.
Unit of randomisation: practice.
Study period: not reported.
Measurement points of outcomes: 3 months and 12 months post intervention.
Analysis method: ITT (reported by study authors).

Participants

Setting
Healthcare setting: primary care (102 primary care practices).
Country: Canada.

Patients
Inclusion/exclusion criteria: all adult patients with nonvalvular atrial fibrillation (diagnosed by their physician and confirmed by electrocardiogram) who were not living in an institution and had no other indication for or a contraindication to warfarin or ASA were identified in participating practices

Numbers of patients: 446.
In intervention: 228.
In comparison: 218.

Characteristics of patients:
• Age: intervention; 73 years (SD = 9), comparison; 71 years (SD = 10).
• Gender: females total 169/434 (39%). Intervention; 95/219 (43%), comparison; 74/215 (34%).
• Health conditions: patients with nonvalvular atrial fibrillation.

Healthcare professionals
Type of healthcare professionals: physicians.
Inclusion/exclusion criteria: not reported.
Numbers of healthcare professionals: not reported.
In intervention: not reported.
In comparison: not reported.

Characteristics of healthcare professionals: not reported.
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

Numbers of primary care practices: 102.
In intervention: 50.
In comparison: 52.

Interventions

Description of patient-mediated intervention: patients received a decision aid consisting of a booklet and audiotape that are designed to be self-administered by patients at home

Patient-mediated intervention category: patient decision aid.

Comparison: usual care (patient information-like). All potential trial participants attended a group tutorial session before enrolment thus being provided with information about nonvalvular atrial fibrillation.

Outcomes

Relevant primary outcomes
The proportion of patients whose therapy met the ACCP treatment recommendations
Measurement: assessed by telephone follow-up with patients and review of their medical, pharmacy and laboratory records

Unit of measurement: absolute numbers.

Relevant secondary outcomes
No relevant outcomes reported.

* Primary outcome in study: short-time effect on proportion of patients whose therapy met the ACCP treatment recommendations. Secondary outcome was the long-time effect on proportion of patients whose therapy met the ACCP treatment recommendations.

Notes

Funding: the Canadian Stroke Network, the Alberta Heritage Foundation for Medical Research (AHFMR), and the University Hospital Foundation, Edmonton

Conflict of interest: none disclosed.

### McKinstry 2006

**Methods**

- **Study design:** randomised trial.
- **Number of study arms:** 2.
- **Unit of randomisation:** patient.
- **Study period:** 1 year starting 2002.
- **Measurement points of outcomes:** 1 year after intervention.
- **Analysis method:** ITT (reported by study authors).

**Participants**

- **Setting**
  - Healthcare setting: primary care (family practice).
  - Country: Scotland.
- **Patients**
  - Inclusion/exclusion criteria: people older than 18 years who had at least one systolic blood pressure recorded > 150 mmHg.
Numbers of patients: 294.
In intervention: 146.
In comparison: 148.

Characteristics of patients:
- Age: intervention; 64 years (SD = 10), comparison; 64 years (SD = 9).
- Gender: females total 181/294 (62%). Intervention; 93/148 (62%), comparison; 88/146 (61%).
- Health conditions: general patient population with high blood pressure.

Healthcare professionals
Type of healthcare professionals: physicians and nurses.
Inclusion/exclusion criteria: not reported.
Numbers of healthcare professionals: not reported.
In intervention: not reported.
In comparison: not reported.
Characteristics of healthcare professionals: not reported.
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

Interventions
Description of patient-mediated intervention: patients were sent: 1) a standard information booklet from the British Hypertension Society (BHS), 2) a detailed guideline, and 3) a record card derived from the Lothian Hypertension Guideline which gave general information about blood pressure, but also provided the patient with clear guidelines as to how their blood pressure should be managed by medical and nursing staff, and a clear exhortation to question their care if the guideline was not being adhered to. The intervention was limited to the distribution of the guideline. Clinical staff members in the practice were fully informed of its content and were told to make use of it if patients took it with them to consultations. However, there was no follow-up mailing or telephone intervention to reinforce its use.

Patient-mediated intervention category: patient information.
Comparison: usual care (patient information-like). Patients were sent a standard information booklet from the British Hypertension Society (BHS) by post.

Outcomes
Relevant primary outcomes:
- Proportion of patients prescribed statins according to guideline
- Proportion of patients prescribed aspirin according to guideline
Measurement: medical record.
Unit of measurement: per cent correct prescriptions.

Relevant secondary outcomes
- Blood pressure (controlled, less than 150/90 mmHg)
- Cholesterol
Measurement: medical record.
Unit of measurement: per cent correct prescriptions.

Anxiety
Depression
Unit of measurement: means.

* Primary outcome in study: average systolic blood pressure.
Secondary outcomes: proportion of patients with blood pressure < 150 mmHg systolic
McKinstry 2006 (Continued)

and < 90 mmHg diastolic, average cholesterol, proportion of patients prescribed statins and aspirin according to guideline, hospital anxiety and depression score

Notes

Funding: Chief Scientist Office of the Scottish Executive.
Conflict of interest: none disclosed.

Miaskowski 2004

Methods

Study design: randomised trial.
Number of study arms: 2.
Unit of randomisation: patient.
Study period: not reported.
Measurement points of outcomes: post intervention (measured over the 6 weeks the study took place and after the intervention)
Analysis method: Not reported.
## Participants

**Setting**  
*Healthcare setting:* hospital (a university-based cancer centre, two community-based oncology practices, one health maintenance organisation, one outpatient radiation therapy centre, one veteran's affairs facility, and one military hospital)  
*Country:* USA.

**Patients**  
*Inclusion/exclusion criteria:* Inclusion: adult oncology outpatients (18 years or older) who were able to read, write, and understand English. All patients had Karnofsky performance scores of 50 or more, average pain intensity scores of 2.5 or more, and radiographic evidence of bone metastasis  
*Numbers of patients:* 174.  
In intervention: 93.  
In comparison: 81.

**Characteristics of patients:**
- **Age:** intervention: 60 years (SD = 11.6), comparison: 58.8 years (SD = 12.9).
- **Gender:** females, intervention: 64/93 (68.8%), comparison: 59/81 (72.8%).
- **Health conditions:** adult patients with cancer pain from bone metastasis.

## Healthcare professionals

**Type of healthcare professionals:** physicians.  
*Inclusion/exclusion criteria:* not reported.  
*Numbers of healthcare professionals:* not reported.

**Characteristics of healthcare professionals:**
- **Age:** not reported.
- **Gender:** not reported.
- **Experience/specialisation:** not reported.

## Interventions

**Description of patient-mediated intervention:** PRO-SELF group patients were seen by specially trained intervention nurses and received a psychoeducational intervention, were taught how to use a pillbox, and were given written instructions on how to communicate with their physician about unrelieved pain and the need for changes in their analgesic prescriptions. Patients were coached during two follow-up home visits and three phone calls on how to improve their cancer pain management

**Patient-mediated intervention category:** patient education.

**Comparison:** usual care (patient information-like). Patients in the standard care arm were seen by a research nurse three times and were called three times by phone between the home visits. Patients in the standard care group received the patient version of the Cancer Pain Guideline published by the Agency for Health Care Policy and Research (AHCPR) and were seen by a research nurse in their homes at weeks 1, 3, and 6. Telephone interviews were conducted at weeks 2, 4, and 5. The focus of the visits and phone calls was on monitoring patients’ level of adherence with completing the diary.

## Outcomes

**Relevant primary outcomes**  
*Appropriate analgesic prescription (around-the-clock (ATC) + as-needed (PRN))*  
*Measurement:* type of opioid prescription (no opioid, only PRN opioid, only ATC opioid, both ATC + PRN opioid)

**Unit of measurement:** Percent.

*Total dose of opioid analgesics prescribed per patient per 24 hours*
Measurement: not reported.
Unit of measurement: changes, from baseline, in total dose of opioid analgesics (mg of morphine) prescribed on a 24-hour basis

Relevant secondary outcomes
Patient outcomes
Different pain intensity measurements:
Average pain
Worst pain
Least pain
Measurement: patient self-report before bedtime for 6 weeks using a descriptive numeric rating scale that ranged from 0 (none) to 10 (excruciating)
Unit of measurement: 1-10 score, mean.

* Primary outcome in study: pain intensity. The secondary outcomes were opioid analgesic intake and appropriate analgesic prescription

Notes
Funding: the National Cancer Institute. Additional funding from Janssen Pharmaceutica and Purdue Pharma LP
Conflict of interest: none disclosed.

### Nagykaldi 2012

#### Methods

- **Study design:** cluster-randomised trial.
- **Number of study arms:** 2.
- **Unit of randomisation:** practice.
- **Study period:** 1 year.
- **Measurement points of outcomes:** post intervention (1 year after intervention started).
- **Analysis method:** ITT (reported by study authors).

#### Participants

- **Setting**
  - **Healthcare setting:** primary care (8 Physicians Resource/Research Network clinicians practices)
  - **Country:** USA.
- **Patients**
  - **Inclusion/exclusion criteria:** Inclusion: patients that had been seen at least twice by the enrolled physician in the last year, were either children (less than 6 years old) or between 40 and 75 years old (women) or 50 and 75 years old (men), could understand and respond in English, and had a basic level of computer skills, and understand/respond to web content phrased at 6th grade level.
  - **Numbers of patients:** 560.
  - In intervention: not reported, but we assume 280 enrolled. No information about the group distribution after lost to follow-up.
  - In comparison: not reported, but we assume 280 enrolled. No information about the group distribution after lost to follow-up.
- **Characteristics of patients:**
  - Age: intervention; 54.6 years, comparison; 50.5 years (no SD provided).
  - Gender: females 328/538 (61%). Intervention; 63%, comparison; 59%.
  - Health conditions: general primary care population.
- **Healthcare professionals**
  - **Type of healthcare professionals:** physicians, nurse practitioners and physician assistants.
  - **Inclusion/exclusion criteria:**
  - **Numbers of healthcare professionals:** not reported.
  - In intervention: not reported.
  - In comparison: not reported.
- **Characteristics of healthcare professionals:**
  - Age: not reported.
  - Gender: insufficient reported (male physicians, female nurses (n = 3)).
  - Experience/specialisation: not reported.

#### Interventions

- **Description of patient-mediated intervention:** patients were offered access to use Wellness Portal—a novel, web-based patient portal that focuses on wellness, prevention, and longitudinal health assistance. They were also encouraged to print their wellness plan and discuss the plan with their physician at their next office visit.
- **Patient-mediated intervention category:** patient information (patient portal).
Comparison: no intervention. Patients in these practices were not given access to the portal and they did not receive personalised recommendations or a wellness plan.

### Outcomes

**Relevant primary outcomes**
- Adults provided all recommended preventive services
- Adults given low dose aspirin, if indicated
- Adults given Pneumococcal vaccination because of chronic health conditions
- Adults given Pneumococcal vaccination because of chronic health conditions
- Children given all recommended immunisations

**Measurement:** patient-reported via the portal web and Medical records of patients (paper and electronic) were reviewed in the practice to determine the number and type of selected preventive services received before and during the 12-month study period

**Unit of measurement:** percent.

**Relevant secondary outcomes**
- No relevant outcomes reported.

### Notes
- We attempted to contact the first author. No reply received.
- **Funding:** not reported.
- **Conflict of interest:** none disclosed.

Quinn 2008

Methods

Study design: randomised trial.
Number of study arms: 2.
Unit of randomisation: patient.
Study period: 2006 (3-month study).
Measurement points of outcomes: post intervention.
Analysis method: not reported.

Participants

Setting
Healthcare setting: primary care (one community endocrinology and two community primary care practices)
Country: USA.

Patients
Inclusion/exclusion criteria: Inclusion: patients 18-70 years old who had a diagnosis of type 2 diabetes for at least 6 months. Study patients were required to have an A1c of 7.5% or more and to have been on a stable diabetes therapeutic regimen for 3 months prior to study enrolment
Numbers of patients: 30.
In intervention: 15.
In comparison: 15.
Characteristics of patients:
• Age: 14 patients between 20-54 years, 12 patients 55-64 years. No group numbers reported.
• Gender: 17/26 females (65.38%). No group numbers reported.
• Health conditions: diabetes type 2.

Healthcare professionals
### Type of healthcare professionals:
- Physicians

### Inclusion/exclusion criteria:
- Not reported

### Numbers of healthcare professionals:
- Not reported

### Characteristics of healthcare professionals:
- Age: Not reported
- Gender: Not reported
- Experience/specialisation: Physician specialty was primary care or endocrinology

### Interventions

**Description of patient-mediated intervention:**
- The intervention group received cell phone-based software that provided real-time feedback on patients’ blood glucose levels, displayed patients’ medication regimens, incorporated hypo- and hyperglycaemia treatment algorithms, and requested additional data needed to evaluate diabetes management.
- Patient data captured and transferred to secure servers were analysed by proprietary statistical algorithms. The system sent computer-generated logbooks (with suggested treatment plans) to intervention patients’ healthcare provider (physician).

**Patient-mediated intervention category:**
- Patient-reported health information about own health/needs/concerns

**Comparison:**
- No intervention (placebo-like). Patients randomised to this group received blood glucose (BG) monitors and adequate BG testing strips and lancets for the duration of the study. They were asked to fax or call in their BG logbooks every 2 weeks to their healthcare provider (physician) until their BG levels were stabilised in the target ranges or until their healthcare provider (physician) changed testing frequency.

### Outcomes

**Relevant primary outcomes**
- Medications titrated or changed by their healthcare provider
- Medication errors identified by their healthcare provider

**Measurement:**
- Medical record

**Unit of measurement:**
- Absolute numbers

**Relevant secondary outcomes**
- **HbA1c**

**Measurement:**
- Medical record

**Unit of measurement:**
- Percent

**Depression diagnosis**
- Measurement: Medical record

**Unit of measurement:**
- Absolute numbers

**Provider diabetes management improved by receipt of blood sugar measurements**
- Measurement: Patient self-report

**Unit of measurement:**
- Absolute numbers

*Primary outcome in study: HbA1c. Secondary outcomes were on healthcare provider (HCP) adherence to prescribing guidelines and HCPs’ adoption of the technology.*

### Notes

**Funding:**
- LifeScan, Inc. and Nokia, Inc.

**Conflict of interest:**
- Not reported

**Thiboutot 2013**

| Study Design | Cluster-randomised trial. |
| Number of study arms | 2. |
| Unit of randomisation | Healthcare professional. |
| Study period | 1 year. |
| Measurement points of outcomes | Post intervention (at end of study (1 year)). |
| Analysis method | ITT (reported by study authors). |

**Participants**

| Setting | Healthcare setting: primary care practices. |
| Country | USA. |
| Patients | Inclusion/exclusion criteria: |
| Inclusion | Age 21 years or older, fluent in English, at least 2 high blood pressure readings in the previous 12 months (130/80 mmHg or higher for patients with diabetes or chronic kidney disease, 140/90 mmHg or higher for patients without), and their physician was participating in the study |
| Exclusion | Receiving care from another physician for hypertension treatment (e.g. cardiologist), hospitalised for a psychiatric disorder in the past 3 years, participating in another clinical research study, pregnant or planned to become pregnant in the next 12 months |
months, planning on moving out of the area in the next 12 months, no personal access to the Internet at home or at work, and no personal email account.

**Numbers of patients:** 500.
In intervention: 282.
In comparison: 218.

**Characteristics of patients:**
- Age: total 60.5 years (SD = 11.9). Intervention; 59.6 years (SD = 12.1), comparison: 61.6 years (SD = 11.4).
- Gender: females total 288/500 (57.6%). Intervention; 165/282 (58.5%), comparison: 123/218 (56.4%).
- Health conditions: general patient population with high blood pressure.

**Healthcare professionals**

*Type of healthcare professionals:* primary care physicians.

*Inclusion/exclusion criteria:* physicians that were board-certified in internal medicine or family practice, did not have specialty training in nephrology or cardiology, were clinically active (at least 50% of their time spent providing direct primary care), were not planning to retire in the next two years, listed as retired, part-time or inactive.

**Numbers of healthcare professionals:** 54.
In intervention: 27.
In comparison: 27.

*Characteristics of healthcare professionals:*
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

### Interventions

**Description of patient-mediated intervention:** patients received a Web-based intervention for 12 months, which included:
1) Web-based hypertension feedback based on the individual patient’s self-report of health variables decision rules, and tailored feedback based on recommendations from JNC 7.
2) a “pocket chart” that patients could print and take to their doctor visits to help them record their blood pressure that could later be entered into the website, and
3) automated reminders that tracked the dates of upcoming visits with their PCP to remind patients to use the website before physician visits. Patients were expected to use the website at least once each month and received reminder emails if 30 days had elapsed since the last time they used the website.

**Patient-mediated intervention category:** patient education.

**Comparison:** usual care (placebo-like). Patients received the same components of the intervention as intervention condition patients (e.g. Web-based personalised feedback, pocket chart, email reminders), but the website focused on preventive services that were not related to hypertension care (e.g. mammography screening, tetanus immunisations) and were recommended by the USPSTF (placebo).

### Outcomes

**Relevant primary outcomes**

*Hypertension screening tests (creatinine, urine protein, serum potassium)*

*Measurement:* medical records.

*Unit of measurement:* absolute numbers.

*Doctor recommended starting a new blood pressure medication*

*Unit of measurement:* absolute numbers.

*Doctor recommended increasing dose of a blood pressure medication*
**Measurement:** patient self-report.
*Unit of measurement:* absolute numbers.

**Relevant secondary outcomes**

**Patient outcomes:**

**Controlled blood pressure**

**Measurement:** medical records.
*Unit of measurement:* absolute numbers.

* Primary outcome in study: change in blood pressure and change in the percentage of patients in each group with controlled blood pressure. Secondary outcomes were hypertension screening tests, lifestyle counselling, and medication intensification.

**Notes**

**Funding:** the National Heart, Lung and Blood Institute. The user interface development was done by Digital Alternatives under contract by authors.

To ensure fidelity to the use of the intervention, patients in both conditions were eligible to receive US $5 for each month they used the website, for a potential total of US $60.

**Conflict of interest:** none disclosed.

### Risk of bias

<table>
<thead>
<tr>
<th>Bias</th>
<th>Authors' judgement</th>
<th>Support for judgement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Random sequence generation (selection bias)</td>
<td>Low risk</td>
<td>The primary care physicians were enrolled and randomised into 1 of 2 conditions by selecting an envelope containing a document with one of the two conditions assigned (intervention or comparison condition) from a stack of sealed envelopes. A statistician generated the order of the envelopes.</td>
</tr>
<tr>
<td>Allocation concealment (selection bias)</td>
<td>Unclear risk</td>
<td>Insufficient information to permit judgement of ‘Low risk’ or ‘High risk’.</td>
</tr>
<tr>
<td>Blinding of participants and personnel (performance bias)</td>
<td>Low risk</td>
<td>To minimise the potential for unblinding physicians, all recruitment letters and discussions with physicians stated that the overall goal of the study was to improve primary and secondary prevention for patients with hypertension.</td>
</tr>
<tr>
<td>Blinding of outcome assessment (detection bias)</td>
<td>Low risk</td>
<td>To reduce the chances that staff would treat patients differently, particularly while assessing outcomes, staff were blinded to the condition of the provider.</td>
</tr>
<tr>
<td>Incomplete outcome data (attrition bias)</td>
<td>Low risk</td>
<td>Low attrition rate. ITT-analysis.</td>
</tr>
</tbody>
</table>
Selective reporting (reporting bias) | Low risk | Protocol is not accounted for, but found on clinicaltrials.gov (NCT00377208). No obvious deviations found.

Other bias | High risk | This is a cluster-randomised trial and thus we have judged additional sources of potential bias:
- Recruitment bias: over 800 physicians contacted and only 54 agreed to participate. Likewise, only 17% of the patients agreed to participate.
- Baseline imbalance: Authors’ quote: “There were no significant differences in most variables between study groups”.
- Loss of clusters: none of the clusters were lost.
- Incorrect analysis: for the five studies in which healthcare professionals were the unit of randomisation, the median ICC among similar studies for our primary outcome was 0.000 (95% CI; 0, 0.142) according to the University of Edinburgh’s Database of ICCs (ABDN 2015). The effective sample sizes of these studies were thus the same as reported by the study authors.
- Comparability with individually randomised trials: no indication that this study had risk of herd-effect bias.
| Interventions | Description of patient-mediated intervention: Patients saw a videotape and received an intervention brochure about the pneumococcal vaccine. The brochure presented minimal information about the vaccine and prompted the patient to ask his/her doctor about the pneumonia shot today.  
**Patient-mediated intervention category:** patient information.  
**Comparison:** usual care (placebo-like). Patients received a brochure about nutrition (The study had a third arm not addressed here consisting of the patient-mediated intervention with a control brochure (nutrition) instead of pneumococcal vaccine brochure). |
| Outcomes | Relevant primary outcomes  
**Primary care physician recommended vaccine**  
**Measurement:** patient self-report.  
**Unit of measurement:** absolute numbers.  
**Relevant secondary outcomes**  
No relevant outcomes reported.  
* Primary outcome in study: discussion of vaccine and patients receiving vaccine. Secondary outcomes were patient read brochure, patient showed brochure to primary care physician, and primary care physician recommended vaccine. |
| Notes | **Funding:** National Vaccine Program and the CDC Emerging Infections Program. Also supported in part by Indigent Care Trust Funds from the State of Georgia to the Office of Health Promotion and Disease Prevention at Grady Health System  
**Conflict of interest:** not reported. |

**Healthcare professionals**  
**Type of healthcare professionals:** primary care physicians.  
**Inclusion/exclusion criteria:** not reported.  
**Numbers of healthcare professionals:** not reported.  
In intervention: not reported.  
In comparison: not reported.  
**Characteristics of healthcare professionals:**  
- Age: not reported.  
- Gender: not reported.  
- Experience/specialisation: not reported.  

**Eligible clinic visits** (such as walk-in visits, first-time visits, and medication refill visits in which patients did not see a provider)  
**Numbers of patients:** 371 (in study n = 558 with 3 arms).  
In intervention: 189.  
In comparison: 182.  
(In arm 3 n = 187).  
**Characteristics of patients:**  
- Age: intervention; 63.4 years (SD = 12.7), comparison; 63.3 years (SD = 12.9).  
- Gender: females total 263/371 (70.9%). Intervention 1; 144/189 (76.2%), comparison; 119/182 (65.4%).  
- Health conditions: general primary care population at risk for complication with a pneumococcal infection.

**Turner 1990**

**Methods**

- **Study design:** randomised trial.
- **Number of study arms:** 2.
- **Unit of randomisation:** healthcare professional.
- **Study period:** Sept 1987 - May 1988
- **Measurement points of outcomes:** post intervention, but not reported exactly time point.
- **Analysis method:** Not reported.

**Participants**

- **Setting**
  - Healthcare setting: outpatient centre.
- **Country:** USA.
- **Patients**
  - **Inclusion/exclusion criteria:** not reported.
Numbers of patients: 423.
In intervention: 177.
In comparison: 246.

Characteristics of patients:
- Age: total 141/423 over 64 years (33.3%). Intervention; 65/177 (37%), comparison; 76/246 (31%).
- Gender: females total 282/423 (66.6%). Intervention; 112/177 (63%), comparison; 710/246 (69%).
- Health conditions: general primary care population.

Healthcare professionals
Type of healthcare professionals: physicians.
Inclusion/exclusion criteria: not reported.
Numbers of healthcare professionals: 24.
In intervention: 12.
In comparison: 12.

Characteristics of healthcare professionals:
- Age: not reported.
- Gender: not reported.
- Experience/specialisation: resident physicians (first second and third year).

Interventions
Description of patient-mediated intervention: patients received a health maintenance prompt card from a clinic receptionist and instructed to keep this card, bring it to all future appointments, and show it to the physician. No attempt was made to educate about health maintenance.

Patient-mediated intervention category: Patient information.

Comparison: no intervention (placebo-like). Patients did not receive prompt cards. A computer-prompting system was instituted to remind all residents to perform a list of preventive measures when indicated.

Outcomes
Relevant primary outcomes
- Pap-smear
- Breast exam
- Mammmography scheduled
- Stool occult test
- Influenza vaccine
- Pneumococcal vaccine

Measurement: medical record.
Unit of measurement: absolute numbers of indicated.

Relevant secondary outcomes
No relevant outcomes reported.
* Primary outcome in study: not reported.

Notes
Funding: North Carolina United Way.
Conflict of interest: not reported.

### Wright 2012

**Methods**

- **Study design:** cluster-randomised trial.
- **Number of study arms:** 2.
- **Unit of randomisation:** practices.
- **Study period:** Sept 2005 - Mar 2007.
- **Measurement points of outcomes:** 60 days post intervention.
- **Analysis method:** ITT and on-treatment (reported by study authors).

**Participants**

- **Setting**: primary care (11 primary care practices).
- **Country**: USA.
- **Patients**
  - **Inclusion/exclusion criteria**: Inclusion: To participate in this study, patients had to have an active Patient gateway account and a primary care provider assigned in the Longitudinal Medical Record (LMR)
  - **Numbers of patients**: 3979 eligible to start with, 856 eligible to receive reminders (indications)
  - In intervention: 396.
  - In comparison: 460.
- **Characteristics of patients:**
  - Age: intervention; 47.0 years (SD = 12.7), comparison; 51.2 years SD = 12.8).
The distribution among the eligible to receive reminders was not reported.

- Gender: intervention; 1432/2,219 (64.5%), comparison; 965/1,760 (54.8). The distribution among the eligible to receive reminders was not reported.
- Health conditions: general adult primary care population.

Healthcare professionals

Type of healthcare professionals: physicians.

Inclusion/exclusion criteria: not reported.

*Numbers of healthcare professionals: 167.*

In intervention: not reported.

In comparison: not reported.

Characteristics of healthcare professionals:

- Age: not reported.
- Gender: not reported.
- Experience/specialisation: not reported.

Practices

*Numbers of practices: 11.*

In intervention: 7.

In comparison: 4.

Interventions

**Description of patient-mediated intervention:** patients with an active Patient gateway account in the intervention arm could receive any of six types of health maintenance reminders as indicated: bone density testing, cholesterol testing, influenza vaccination, mammography, Pap smear and pneumococcal vaccination. Information was transmitted to the LMR, through which the patient's PCP could review eJournals and order screenings. Providers received reminders when a patient was due for a health maintenance procedure.

**Patient-mediated intervention category:** patient information.

**Comparison:** usual care (placebo-like). Patients in the active control arm were invited to complete eJournals that allowed them to review and modify medication and allergy lists and diabetes management information (placebo). Providers received reminders when a patient was due for a health maintenance procedure. The primary difference between the arms was the content of the modules patients reviewed after opening an eJournal.

Outcomes

**Relevant primary outcomes**

- Influenza vaccines
- Mammography
- Pap smears
- Pneumovax
- Bone density
- Cholesterol

**Measurement:** not reported, but most likely medical record.

**Unit of measurement:** absolute numbers of those indicated.

**Relevant secondary outcomes**

No relevant outcomes reported.

* Primary outcomes in study: adherence to guideline-based care recommendations (all outcomes here within)

Notes

**Funding:** AHRQ.

**Conflict of interest:** none disclosed.
**Risk of bias**

Copyright © 2018 The Cochrane Collaboration. Published by John Wiley & Sons, Ltd.
NCT02686775  (Continued)

- Referred for further treatment at the oncology ward OR
- Must either 1) Live alone (irrespective of education) or 2) Have no formal education beyond secondary school, or 3) Have one or more co-morbidities, or 4) a performance status of 1-2, or 5) be more than 65 years old at time of inclusion.

**Exclusion Criteria:**
- Dementia
- Being institutionalised
- No proficiency of Danish

| Interventions | Intervention: patient coach: 5 face-to-face sessions of approximately 1-2 hours duration and 3 phone calls from inclusion to one month after end of first line treatment. Deviations from this schedule might depend on the treatment modules and on the wishes and needs of the patient. Several patients will continue directly into palliative care and the coach will thus support this transition
| Comparison: standard care |

| Outcomes | Primary Outcomes
Receipt of first-line treatment according to clinical guidelines |

| Starting date | January 2016 |

| Contact information | Principal Investigator: Susanne O Dalton, Danish Cancer Society Research Center, sanne@cancer.dk |

| Notes | Status September 2017: Currently recruiting participants |

CBPR: Community-Based Participatory Research
CRC: colorectal cancer
RCT: randomised trial
## DATA AND ANALYSES

### Comparison 1. Patient-reported health information interventions versus comparisons

## Examples of patient-mediated interventions

<table>
<thead>
<tr>
<th>Examples of different types of patient-mediated interventions</th>
<th>An example</th>
<th>Possible mechanisms of action</th>
<th>How it might have positive effects</th>
<th>How it might have adverse effects</th>
</tr>
</thead>
<tbody>
<tr>
<td>Patient-reported health information about own health/needs/concerns or other relevant outcomes (collecting information from patients and giving it to professionals before, or during a clinical encounter)</td>
<td>The patient or carer completes a questionnaire or form in the waiting area before a consultation. The doctor is then given this information before or during the consultation</td>
<td>Information to healthcare professionals from patients → clinical encounter → impact on healthcare professionals’ performance</td>
<td>Information from patients about own health/needs/concerns might ensure that professionals get important information that they might otherwise not have received. This information might prompt professionals to improve their practice and provide recommended health care</td>
<td>This might distract healthcare professionals from focusing on other things or lead to longer consultations without measurable improvements in the quality of care, if the information that is collected turns out not to be important</td>
</tr>
<tr>
<td>Patient information where patients are informed about recommended care</td>
<td>The patient is given a brochure with information about cancer screening</td>
<td>Information to patient from others → clinical encounter → impact on healthcare professionals’ performance</td>
<td>Giving recommendations or evidence to patients might lead them to ask for recommended care, and professionals might respond by providing it</td>
<td>Healthcare professionals might feel threatened by this or disagree with the information given to patients. Patients might become distrustful of the healthcare professionals</td>
</tr>
<tr>
<td>Patient education/training/counselling to increase patients’ knowledge about their condition</td>
<td>The patient signs up for a group-based self-management program where she is provided with information about her condition and becomes part of a patient group for sharing of experiences to increase self-efficacy and coping</td>
<td>Activation of patient by others → clinical encounter → impact on healthcare professionals’ performance</td>
<td>Education/training/counselling to increase patients’ knowledge about their condition, which can increasing their self-efficacy and self-care skills. This in turn, might encourage patients to get more involved in decisions about their treatment and management and professionals might respond by providing recommended health care</td>
<td>Healthcare professionals might feel threatened by this or disagree with the patient. It might increase healthcare professionals’ burden if they need to spend more time finding answers to patients’ questions. Patients might feel more uncomfortable if they have more questions but do not feel comfortable asking them. Patients might not like the answers they are given. This might lead to longer consultations without measurable improvements in the quality of care</td>
</tr>
<tr>
<td>Patient feedback about clinical practice (collecting information from patients after an encounter)</td>
<td>After the patient has used a healthcare service, she might be asked about her experience with the service or doctor. This information is then fed back to the doctors and/or hospital</td>
<td>Information to healthcare professionals from patients → impact on healthcare professionals' performance</td>
<td>Clinical performance feedback from patients might ensure that professionals get important information that they might otherwise not have received. This information might prompt professionals to improve their practice and provide recommended health care This might distract healthcare professionals from focusing on other things or lead to longer consultations without measurable improvements in the quality of care, if the information that is collected turns out not to be important</td>
<td></td>
</tr>
<tr>
<td>Patient decision aids to ensure that the choices about treatment and management reflect recommended care and the patients' values and preferences</td>
<td>The patient is provided with information about treatment options including risks and benefits. The patient considers this information, either alone or with a healthcare professional, to reach a decision in accordance with her values and preferences</td>
<td>Activation of patient by others → clinical encounter → impact on healthcare professionals' performance</td>
<td>Giving recommendations or evidence to patients and encouraging them to engage with their own values and preferences for treatment options might encourage healthcare professionals to provide recommended health care Healthcare professionals might feel threatened by this or disagree with the patient. It might increase healthcare professionals’ burden if they need to spend more time finding answers to patients’ questions. Patients might feel more uncomfortable if they have more questions but do not feel comfortable asking them. Patients might not like the answers they are given. This might lead to longer consultations without measurable improvements in the quality of care</td>
<td></td>
</tr>
<tr>
<td>Patients, or patient representatives, being members of a committee or board</td>
<td>A patient representative from a patient organisation is, on behalf of a patient group, part of a hospital board. The board may discuss patient care and make decisions about professional practice within the hospital</td>
<td>Information to healthcare professionals from patients → committee or board meeting → impact on healthcare professionals' performance</td>
<td>Patients being part of a prioritisation or agenda deciding process at the health system level might influence professional practice and result in giving patients the recommended health care Healthcare professionals on the committee or board might feel threatened by this or disagree with the patients’ prioritisation or decisions. This might in turn, lead to poor implementation of recommendations or guidelines made within this format</td>
<td></td>
</tr>
<tr>
<td>Patient-led training or education of healthcare professionals</td>
<td>Patients taking part in training of doctors, e.g. to improve communication</td>
<td>Information and/or activation of healthcare professionals by patients</td>
<td>Patients being part of the education or training of healthcare professionals Healthcare professionals might feel threatened by this or disagree with the</td>

In calculating the costs, we used an hourly wage of $15 for a clerical employee. There were 6 calls per child per year resulting in a cost of $60. We estimated $10 for supplies and informational materials for the PCP. Because some PCPs had 1 child in the study, the cost for these materials on a per child basis was $9.20. The intervention was estimated to cost $69.20 per child over the year. When this cost was added to the cost of health services use for the year by intervention children and compared with the cost of health service use by control children, there was a savings of $337.00 per child in the intervention group. The Monte Carlo simulations, using the observed distributions of symptom days and resource use, showed that the intervention had a 97% chance of being cost saving.” |

CONTRIBUTIONS OF AUTHORS

MSF led the work with and wrote the protocol, performed some of the searches, screened studies for inclusion, extracted data, assessed risk of bias, assessed certainty of the evidence (GRADE), and drafted the review.

TKD assisted with the protocol, screened studies for inclusion, extracted data, assessed risk of bias, assessed certainty of the evidence (GRADE), and commented on drafts of the review.

AF assisted with the protocol, assisted with screening of studies for inclusion, and commented on drafts of the review.

MJ designed and carried out most of the searches.

SF provided general advices on the protocol and commented on drafts of the review.

HS provided general advices on the protocol and commented on drafts of the review.
